There are several generally held misconceptions concerning the pectoral girdle of modern birds. The most prevalent of these is that the carina of the sternum is the principal site of origin of the massive pectoralis muscle, which provides the power stroke of the wing. This is not so. In most birds, *m. pectoralis* originates to a greater extent from the furcula and the coraco-clavicular membrane (Fig. 1). As it passes posteriorly its fibres originate on the sternum only from those areas not pre-empted by the underlying *m. supracoracoideus*. Typically, these areas consist of a narrow band on the ventral margin of the carina and the most lateral and posterior portions of the sternal plate (Fig. 2). In such birds as the *Dendrocolaptidae*, in which the carina is reduced to facilitate tree-trunk foraging⁷, the pectoralis muscle becomes thin and broad, spreading out laterally and dorsally well past the sternum and on to the rib cage. Once anchored to the furcular area, it would seem that *m. pectoralis* could expand posteriorly and attach to any underlying structure that happened to be present.

Apart from feathers, the character of *Archaeopteryx* most often cited as being bird-like is the well developed furcula. Relative to modern birds of the same size, the furcula of *Archaeopteryx* is actually hypertrophied. There has been no satisfactory explanation of this structure which has received mostly perfunctory treatment. Ostrom merely asks: "Did it function as a transverse spacer between the shoulder sockets?"² Why such a structure would be needed in *Archaeopteryx* and not in any of its suggested ancestors is never dealt with. We consider that the extremely robust furcula of *Archaeopteryx* is best interpreted as having been the site of origin of a well developed pectoralis muscle.

When it is observed that *m. pectoralis* arises to a large extent from the furcular area, it can then be seen that the main function of the ossified sternum and carina in modern birds is to provide attachment for the supracoracoideus muscle (Fig. 2). Although the belly of *m. supracoracoideus* is situated ventrally, it serves to raise the wing because its tendon passes above the glenoid facet and over the acrocoracoid process of the coracoid to insert on the dorsal aspect of the humerus (Fig. 2). In modern birds it is the largest of the muscles that effect the recovery stroke of the wing. For this reason, Ostrom² has emphasised the absence of an acrocoracoid process in *Archaeopteryx*, suggesting that if *m. supracoracoideus* had been present it could not have functioned to raise the wing. Ostrom interprets this as evidence for *Archaeopteryx* having been flightless, the implication being that *m. supracoracoideus* is essential for flight. That this is not the case has been conclusively proven by Sy⁸, who cut the supracoracoideus tendons in living examples of crows (*Corvus*) and pigeons (*Columba*) and found that the birds were still capable of normal, sustained flight. It is of considerable interest that the only capacity lost was the ability of the pigeon to take off from level ground.

It has thus been proved that in modern birds the dorsal elevators (principally *m. deltoideus major*⁸) are completely capable of effecting the recovery stroke of the wing. These

Fig. 1 Left side of pectoral girdle of the duck *Bucephala clangula* showing the furcula and extensive coraco-clavicular membrane from which *m. pectoralis* has its main origin (redrawn from Sy⁸).

Fig. 2 Right side of pectoral girdle of the pigeon *Columba livia* to show the action of *m. supracoracoideus* and the extensive area of the sternum that this muscle occupies. *M. pectoralis* attaches to the sternum only on those areas shown in stipple. (Modified from Ostrom², after George and Berger¹⁰.)

muscles originate mainly from the scapula, which in *Archaeopteryx* forms an acute angle with the coracoid, as is true in adults of modern flying birds. The acute angle shortens the distance through which the dorsal elevators must act, thus giving greater power. In most flightless birds, on the other hand, the acute angle is lost and the scapula is more nearly vertical⁹.

The dorsal musculature is present and is used to raise the forelimb in virtually all vertebrates; furthermore, it is the dorsal musculature that elevates the wing in such volant forms as bats. Therefore, it is logical to assume that in the evolution of avian flight the recovery stroke of the wing would first have been carried out by the dorsal elevators. The enlarged, ventrally situated *m. supracoracoideus*, the acrocoracoid process, and the ossified sternum with a keel, constitute a single functional complex that is not a requisite of flight but merely a refinement that was superimposed in later birds on an apparatus probably already capable of full flight. The enlarged *m. supracoracoideus* probably evolved to counter the action of an increasingly enlarged *m. pectoralis* and, as evidenced by Sy's experimental pigeons, may have been necessary for birds to adopt purely terrestrial habits.

In conclusion, the robust furcula of *Archaeopteryx* would have provided a suitable point of origin for a well developed pectoralis muscle. Furthermore, the supracoracoideus muscle, and hence an ossified sternum, is not necessary to effect the recovery stroke of the wing. Thus the main evidence for *Archaeopteryx* having been a terrestrial, cursorial predator is invalidated. There is nothing in the structure of the pectoral girdle of *Archaeopteryx* that would preclude its having been a powered flier.

A new kind of neural superposition eye: the compound eye of male Bibionidae

IN neural superposition eyes the signals of receptors pointing to one region in space are neurally pooled. The optical and neural organisation of these eyes yields an enhanced absolute light sensitivity while minimising the loss of visual acuity that accompanies pooling. In the compound eyes of flies (Diptera), this is achieved in the following way. The distal endings of seven retinula cells lie near the back focal plane of each lens¹. Their light-sensitive structures, the rhabdomeres, are optically isolated from each other. The rhabdomeres of one ommatidium have different optical axes. The optical axes of seven rhabdomeres in seven adjacent ommatidia are parallel (Fig. 1a, ref. 2). The axons of such retinula cells (except the central ones, which pass through to the second optic ganglion) converge onto the same cartridge of secondary neurones in the first optic ganglion, the lamina^{3,4}. Thus, each lamina cartridge 'looks at' one point in space. In one suborder of flies (Cyclorhapha), to which the housefly *Musca* and the fruitfly *Drosophila* belong, the arrangement of rhabdomeres is asymmetrical (Fig. 1a). Eyes organised in this way are one form of neural superposition eyes². Here, I provide evidence that a different kind of neural superposition eye exists in the Bibionidae, a family of flies of the suborder Nematocera. Bibionids are peculiar in being extremely sexually dimorphic in their visual system: the males have, in addition to small 'female' eyes, a pair of large dorsal compound eyes, functionally correlated presumably with the male habit of swarming and chasing females. These dorsal eyes differ from the eyes described in more advanced flies in two respects: the rhabdomeres are symmetrically arranged and the rhabdomeres with parallel optical axes are found in ommatidia $\sqrt{3}$ times further apart than adjacent ommatidia. The course of the retinula cell axons in the lamina differs accordingly.

Fig. 1 Arrangement of rhabdomeres and optical organisation of the compound eyes of *a*, cyclorhaphan flies (after Kirschfeld²) and *b*, nematoceran flies (Bibionidae). Rhabdomeres marked with large dots have parallel optical axes. Arrows in *b* show the initial course of retinula cell axons in the lamina, as predicted from optical data.

The technique of antidromic illumination⁵ was used to investigate the optical organisation of the eye. The flies are immobilised with beeswax, and light shone into the ventral side of the head, where a small window has been cut into the cuticle. In this experimental situation, light is diffusely scattered inside the head and travels antidromically up the rhabdomeres, which function as light guides. The distal tips of the rhabdomeres thus become light sources in the back focal plane of each lens. Real and virtual images of the rhabdomere tips can be observed with a microscope, focused at different levels above and below the cornea. Anatomical data were derived from reduced silver preparations⁶.

Fig. 2 *a*, Geometrical construction to show the relationship between size and depth of the deep pseudopupil (DPP), the inter-ommatidial angle, $\Delta\phi_0$, and the angle between rhabdomeres, $\Delta\phi_r$. *c*, Cornea; *n*, nodal point; *rh*, distal tips of rhabdomeres. Not drawn to scale. Histological data for *Bibio marci* are as follows (after correction for 15% shrinkage). Radius of curvature of lens, 23.1 μm ; distance of rhabdomere tips from the lens surface, 82.8 μm ; separation of rhabdomere tips, 3.0 μm . The angle subtended by the rhabdomeres at the nodal point is 2.88° , assuming the nodal point to lie in the centre of curvature of the lens (this is the case when the air-cuticle interface alone provides the refractive power of the lens). This agrees well with the optical data listed below. *b*, Pattern of lenses at the level of the cornea. Except for the area shown, the eye is covered with black ink to reduce stray light. Mean distance of adjacent facets, 32.96 μm . The inter-ommatidial angle is given by $\tan \Delta\phi_0 = 32.96/1,100$. $\Delta\phi_0 = 1.72^\circ$. The separation of facets $\sqrt{3}$ times further apart (like those marked in Fig. 1*b*), 55.86 μm . The angle, $\Delta\phi'_0$, between these facets is 2.91° . *c*, Deep pseudopupil. Superposition of virtual images of the distal tips of rhabdomeres at the centre of local curvature of the eye, 1,100 μm below the cornea. Mean distance of the peripheral images from the central one, 55.48 μm . The angle between rhabdomeres is given by $\tan \Delta\phi_r = 55.48/1,100$. $\Delta\phi_r = 2.89^\circ$. Photographs taken through a Leitz Orthoplan microscope, antidromic illumination, male *Bibio marci*.

Fig. 3 Hypothesised course and distribution of retinula cell connections in the lamina of male bibionids. Circles represent horizontal views of cartridges. *a*, Divergence of axons from one ommatidium to six different cartridges, corresponding to six different optical axes. Note that the axons have to turn $\sim 180^\circ$ and that they have to pass between two neighbouring cartridges to reach the appropriate one. *b*, Convergence of axons transmitting information about the same region in space, that is, axons of retinula cells having parallel optical axes. Note that these converging axons take the same routes as the divergent ones. *c*, Divergent and convergent axons drawn in one diagram. The fibres form a hexagonal lattice with the same orientation as the corneal lattice of lenses. Histological examination (Fig. 4) indicates that it is not the axons, but their collaterals, that form this network of connections.

Fig. 4 Transverse section through the lamina, showing the network of axon collaterals of retinula cell axons. Triads in the corners of the lattice are profiles of main axons running perpendicular to the plane of sectioning down into the lamina. The pattern of fibres is strikingly different from that seen in other flies^{3,4}. Bar, 10 μ m; Bodian silver; *Bibio marci*.

The optical axes of the ommatidia (that is, of their central rhabdomeres) intersect at the centre of curvature of the eye (Fig. 2a). At this point (1,100 μ m beneath the cornea in the case of the male eye of *Bibio marci*) the microscope visualises an enlarged image of the receptor endings, originating from the superposition of virtual images of the rhabdomere tips thrown by each lens along its optical axis (Fig. 2b). This image has been termed the deep pseudopupil (DPP, refs 7, 8). The distance of the DPP from the cornea is determined by the inter-ommatidial angle, $\Delta\phi_0$, and its size is a function of the inter-rhabdomere angle, $\Delta\phi_r$ (Fig. 2a, refs 7, 8). In bibionids, which have a symmetrical arrangement of rhabdomeres typical of nematoceran flies^{9,10}, the size of the DPP exactly matches the size of the lens pattern shown in Fig. 1b (Fig. 2b). This means that for the arrangement of ommatidia marked in Fig. 1b the inter-ommatidial angle, $\Delta\phi'_0$ (which is $\sqrt{3}$ times the angle, $\Delta\phi_0$, between adjacent ommatidia), is equal to the angle between rhabdomeres. Every seven rhabdomeres, having relative positions like those marked in Fig. 1b, point in the same direction in space. It follows that the optical requirements of a neural superposition eye are fulfilled.

It remains to be shown, however, that the neural conditions are met: that is, that the axons of retinula cells with parallel optical axes converge onto the same cartridge (set of secondary neurones) in the lamina. Given the optical organisation outlined above, a hypothesis can be advanced about the anatomical organisation of the retina-lamina projection (Fig. 3). Two outstanding and easily testable features of the projection emerge from this hypothesis: (1) to reach their respective cartridges, the axons of the six peripheral retinula cells in one ommatidium have to twist through 180° and diverge in opposite directions, and (2) the axons or their collaterals have to pass between cartridges, forming a hexagonal network.

In horizontal histological sections the axons of the retinula cells, leaving the retina in tight bundles, can be seen to rotate about 180° on entering the lamina. In crossing the superficial layer of cell bodies of lamina neurones, the axon bundles open up. This brings three axons of three adjacent ommatidia into close proximity (see Fig. 1b). The clusters of three axons run down into the lamina, parallel to the long axes of the cartridges, marking the corners of a hexagonal lattice in horizontal sections. In the course of running down into the lamina, the axons give off collaterals, which pass between adjacent cartridges towards the ones in the next row. These collaterals form a hexagonal

network of fibres which have the same orientation as the corneal pattern of hexagonal lenses (Fig. 4). Therefore, it seems to be these collaterals which establish connections with the appropriate cartridges. At the level of light microscopy, the anatomical structure of the lamina therefore agrees with the predictions made, based on the optical structure of the retina.

Up to now neural superposition eyes have been found in only one other order of insects. Although in this case (Hemiptera¹¹) the retina-lamina projection has not been described in detail, the optical organisation is quite different from that of dipteran eyes. The rhabdomeres with parallel optical axes lie in ommatidia even further apart (3–4 facets) than in the case of the nematoceran flies described here. This raises several questions about the evolution of neural superposition eyes. Within Diptera, at least, we may ask what functional and/or structural reasons might have caused the topological rearrangement from the symmetrical, widely spaced organisation of a nematoceran eye to the asymmetrical one of flies considered to be more advanced in evolution.

I thank Professor D. Varjú for loan of equipment and support, Dr M. Land for reading and discussing the manuscript, F. Burton, M. Pisana and Dr N. Strausfeld for histological advice, and C. Atherton for photographic assistance. Financial support came from an SRC grant to Dr M. Land and from GRAFÖG, Universität Tübingen.

The role of inner hair cells in hearing

DISCUSSION about functional differences between the inner and outer hair cells (IHCs and OHCs) in the mammalian organ of Corti^{1–5}, has arisen as a result of several anatomical and electrophysiological observations. The proportions of afferent and efferent fibres supplying the two types of cells are quite different^{6–8}; the afferent neurones associated with them are distinct cytologically as well as in their susceptibility to retrograde degeneration^{6–8}; the electrophysiological responses following preferential loss of OHCs are not what would be expected on the basis of a similarity of function^{2,5,9–11}. Attempts at the elucidation of these differences^{2,9} have made use of the ototoxic antibiotic kanamycin, which causes preferential damage to OHCs. This technique is far from ideal: the damage may be patchy and IHCs may also be affected. As to the selective elimination of IHCs, no procedure has been available. Mutant genes frequently provide material that cannot be produced experimentally, but although a large number of genes affecting the inner ear in various ways are known in the mouse^{12–14}, there

has been none so far that clearly discriminated between IHCs and OHCs. We now report a new mutation in the mouse which selectively eliminates IHCs. As the mutant animals are almost totally deaf, it would seem that hearing is predominantly dependent on IHCs.

The new mutation occurred at Albert Einstein College of Medicine, Bronx. It is an autosomal recessive gene with full penetrance. The homozygotes show an abnormality of behaviour that is known as the waltzing syndrome¹², and to conform with general usage the gene has been named *bronx waltzer* and assigned the symbol *bv*. The hearing ability of *bv/bv* mice is severely impaired. The affected animals either give no response to sound at all or respond very slightly during a short period following the normal time of onset of hearing (at about 13 d). The hearing tests were based on Preyer's pinna reflex.

Fig. 1 Organ of Corti in newborn mice. *a*, $+/+$; IHC normal. *b*, *bv/bv*; IHC absent. *c*, *bv/bv*; IHC abnormal.

This method is far from refined, but experience has shown that it is reliable enough for preliminary studies. Moreover, the results of these tests were subsequently confirmed by the severe degeneration of the spiral ganglion, observed even in very young animals.

Altogether, 31 *bv/bv* animals, ranging in age from newborn to 281 d old, and 14 normal controls ($4+/bv$, $10+/+$), ranging from newborn to 253 d old, were used in this study. They were fixed in Witmaack's fluid by intravital perfusion, and the heads were decalcified in 1% nitric acid. The otic capsules, with the surrounding tissues intact, were embedded in celloidin, impregnated with paraffin wax, and sectioned at 10 μ m in a plane parallel to the modiolus. The sections were stained with Ehrlich's haematoxylin and orange G containing a trace of erythrosin.

The gross structure of the cochlea in *bv/bv* mice is normal. Histological abnormalities occur in the organ of Corti and the spiral ganglion. Other structures, including the stria vascularis, seem to be normal. In the organ of Corti the pillars and IHCs may be absent or malformed. As the pillars are formed well after birth, their abnormalities appear later, but those of IHCs are clearly visible even in the newborn (Fig. 1). A large proportion

Fig. 2 Distribution of normal (large spot), abnormal (small spot) and missing (no spot) IHCs in 30 consecutive sections from the middle part of the left cochlea. *a*, $+/+$; newborn. *b*, $+/+$; 241 d old. *c*, *bv/bv*; newborn. *d*, *bv/bv*; 3 d. *e*, *bv/bv*; 6 d. *f*, *bv/bv*; 9 d. *g*, *bv/bv*; 29 d. *h*, *bv/bv*; 150 d. *i*, *bv/bv*; 244 d.

of IHCs are not formed at all, and of those that are formed the vast majority are grossly abnormal. They may be very small and rounded or they may occur in strikingly abnormal positions. There may in some cases be two abnormal cells side by side instead of a single normal one. However, occasional IHCs are observed that are normal in appearance and position. Further study would be required to determine whether they actually are normal. These apparently normal cells had a tendency to disappear with age, although some remain even in the oldest animals studied. To determine the distribution of the normal, abnormal and missing IHCs, 30 consecutive sections from the middle part of the cochlea were examined in both the ears of 12 animals ranging in age from newborn to 244 d old. Figure 2 shows the distributions observed in the left ears of a representative sample. The two sides were generally very similar.

The density of the neurones in the spiral ganglion seems to be approximately normal in the newborn, but their degeneration is so rapid that the ganglion is obviously thinner by 6 d, and after about 4 months very few cells remain in it (Fig. 3). Specialised techniques would be required to determine the type of the remaining cells and whether they are normal, but as far as the extent of the degeneration is concerned, it is consistent with Spöndlin's⁶⁻⁸ finding that in the cat >90% of all spiral ganglion cells innervate IHCs, and are subject to retrograde degeneration.

As to OHCs, some may be a little irregular in shape, and an occasional cell may even be missing, but generally they seem to be normal. It is assumed that they are also normal in function,

Fig. 3 Organ of Corti and spiral ganglion (SG) of a 150-d-old *bv/bv* mouse showing the absence of IHC and degeneration of SG.

not only because they do not degenerate but also because the tunnel fibres leading to them are intact even in the oldest animals.

These findings suggest that 'basic' hearing is predominantly, if not wholly, dependent on IHCs. OHCs may take part in further discriminatory processes or may even govern the IHCs in some way, but they are incapable of leading to the development of normal hearing ability on their own. Further work on this mutant using specialised techniques may lead to a clearer understanding of the functional differences between IHCs and OHCs.

This gene also affects the vestibular part of the inner ear, but this is not believed to be the cause of the 'waltzing' behaviour. Investigations on a large number of other mutants with this type of behaviour suggest that its cause should be sought in the central nervous system and not in the inner ear¹⁵.

Dopamine inhibits adenylate cyclase in human prolactin-secreting pituitary adenomas

THERE is evidence for the existence of multiple forms of dopamine (DA) receptors¹⁻³. In particular, some of these receptors are coupled to adenylate cyclase (DA-stimulating enzyme activity), whereas others seem to be independent³⁻⁵. These two classes of receptors, which have been designated D-1 and D-2, respectively, would also have different pharmacological properties⁶. Pituitary mammothroph DA receptors regulating prolactin (PRL) secretion are considered to be typical D-2 receptors. A DA-stimulated adenylate cyclase has not been detected in normal anterior pituitaries^{3,5,6}; furthermore, several studies indicate that cyclic AMP is stimulatory and not inhibitory to PRL secretion^{7,8}. We report here that in homogenates of human PRL adenomas, in which dopaminergic agonists act as inhibitors of PRL secretion, basal adenylate cyclase is inhibited by DA. The DA receptors mediating this inhibition have the

same pharmacological properties as those regulating PRL secretion.

Adenomas were surgically removed from hyperprolactinaemic patients through the transnasosphenoidal route. The adenomatous nature of the surgical fragments was confirmed both by histological examination and by SDS-polyacrylamide gel electrophoretic analysis⁹ of the homogenates used for the adenylate cyclase assay. The latter revealed in all cases a prominent PRL content, whereas growth hormone, which in the electrophoretograms of normal human anterior pituitaries gives a major band (our unpublished observations), was absent. The preoperative plasma levels of PRL and the effects on these levels of dopaminergic agents are shown in Table 1. In six out of the seven cases examined, dopaminergic drugs were clearly inhibitory. Moreover, *in vitro* perfusion experiments carried out in separate adenomas revealed that such inhibition is due, at least partially, to a direct effect of DA on adenoma cells (Fig. 1).

Fig. 1 *In vitro* release of PRL from a human PRL adenoma. Adenoma fragments were immersed, immediately after surgical removal, in minimum essential medium (MEM) at ice temperature and kept as such until they were mounted in a superfusion apparatus³⁰ (within 2 h of the operation). Perfusion was carried out at 37°C with MEM gassed with an oxygen/carbon dioxide (95%/5% w/v) mixture. Fractions were collected every 3 min starting at 90 min after the beginning of the superfusion. During the periods indicated by the horizontal bars the superfusion medium contained 5.5 mM theophylline or 10 µM DA. Duplicate aliquots of the superfusate fractions were analysed for the PRL content by radioimmunoassay. Theophylline, which increases the intracellular levels of cyclic AMP through a blockade of phosphodiesterase, is stimulatory on secretion, whereas DA is strongly inhibitory. Before adenomectomy the plasma PRL concentration was 70 ng ml⁻¹ and this was reduced by more than 50% by the administration of dopaminergic drugs (see legend to Table 1). The radioimmunoassay for PRL was carried out according to Sinha *et al.*²⁸.

Table 1 also shows the effect of 10 µM DA on basal adenylate cyclase in homogenates of individual adenomas. The inhibitory effect of DA on adenylate cyclase *in vitro* parallels the effect of dopaminergic agents on PRL secretion *in vivo*. The action of DA was dose dependent (Fig. 2a, b), with IC₅₀ values of 3 × 10⁻⁷–10⁻⁵ M in individual cases. The inhibitory effect of DA on adenylate cyclase is mimicked by the dopaminergic ergot, CH-29-717 (Sandoz) (a potent water-soluble analogue of CB-154, (ref. 10)), and by (-)-noradrenaline (NA) (Fig. 2b, c). In agreement with *in vitro* studies on PRL secretion and on binding of dopaminergic drugs to pituitary membranes carried out in animal pituitaries¹¹⁻¹⁵, NA is less potent than DA, but CH-29-717 is effective at even lower concentrations than DA. The specificity of the DA action was confirmed from the effects of the dopaminergic antagonists. In the responsive cases, low doses of drugs of the phenothiazine group (trifluoperazine and fluphenazine) had no effect on basal adenylate cyclase, but

Table 1 Effect of dopaminergic drugs on PRL secretion *in vivo* and of DA on basal adenylate cyclase *in vitro*

Case	PRL plasma levels before adenomectomy		Adenylate cyclase activity		
	Basal levels (ng ml ⁻¹)	% Reduction induced by administration of dopaminergic drugs	Cyclic AMP formed (pmol per mg protein per 3 min)		% Variation induced by 10 μ M dopamine
			Control	Dopamine	
1	95	>50%	165.52 $\pm$ 13.76	111.76 $\pm$ 8.31*	-32.48
2	120	>50%	204.56 $\pm$ 17.14	144.40 $\pm$ 4.76*	-29.41
3	90	>50%	193.60 $\pm$ 1.60	118.08 $\pm$ 1.16*	-39.41
4	65	>50%	53.44 $\pm$ 0.78	45.84 $\pm$ 2.00*	-14.22
5	72	>50%	112.48 $\pm$ 2.37	89.11 $\pm$ 7.68*	-20.77
6	120	>50%	50.79 $\pm$ 1.59	44.21 $\pm$ 0.66*	-12.95
7	200	No effect	55.69 $\pm$ 1.30	56.98 $\pm$ 1.67	No effect

Patients were infused with DA (2 μ g per kg per min $\times$ 3 h) or given CB-154 (Sandoz) (5 mg orally). Plasma levels of PRL were evaluated either at the end of the infusion, or after the CB-154 administration. For the enzyme assay, adenoma fragments were frozen to -20 °C immediately after surgical removal and thawed only just before the assay (4-15 d later). They were homogenised in 20 vol (w/v) of 2 mM Tris-maleate buffer, pH 7.4, containing 2 mM EGTA. The final incubation mixture (0.1 ml) contained: 80 mM Tris-maleate pH 7.4, 10 mM theophylline, 1 mM cyclic AMP, 0.2 mM EGTA, 0.15 mM [¹⁴C]-ATP (20 mCi mmol⁻¹) (except in cases 1 and 2 where [¹⁴C]-ATP was 0.5 mM), MgSO₄ (2 mM in cases 1 and 2, 0.6 mM in case 3 and 1.5 mM in all other cases), phosphocreatine (1.8 mg ml⁻¹) and creatinephosphokinase (7 U ml⁻¹). Protein concentration varied between 0.4 and 1 mg ml⁻¹. The reaction was started by the addition of the homogenate, carried out for 8 min at 30 °C and stopped by a solution containing 2% SDS, 1.4 mM cyclic AMP and 40 mM ATP. Biochemical assays were carried out according to the following procedures: adenylate cyclase, ref. 27; PRL, ref. 28; protein, ref. 29. Values for adenylate cyclase activity represent the mean $\pm$ s.e.m. of at least three replicate samples.

* $P < 0.05$, † $P < 0.001$; ‡ $P < 0.025$.

competitively antagonised the inhibitory action of DA (Fig. 2a). The DA effect was also blocked by (-)-sulpiride (Ravizza), an antagonist of mammotroph DA receptors^{11,14,15}. In case 7, dopaminergic agents failed to decrease PRL plasma levels, and DA was without effect on the basal adenylate cyclase activity of the homogenate. However, in this case, adenylate cyclase was stimulated by low doses of phenothiazines¹⁶ and such stimulation was competitively counteracted by DA (Table 2). Thus, even in case 7, DA has a potential ability to inhibit adenylate cyclase.

Our results, which indicate a striking similarity between DA receptors mediating adenylate cyclase inhibition and DA receptors inhibiting PRL secretion, suggest that a decrease in the intracellular concentration of cyclic AMP might mediate the action of DA in mammotrophs. Doses required to inhibit adenylate cyclase are higher than those which are known from *in vitro* studies on animal pituitaries to be effective on PRL secretion^{12,13}; however, in other systems also, discrepancies

have often been observed between the drug concentrations which elicit physiological responses thought to be mediated by cyclic AMP, and those required to modulate the adenylate cyclase-cyclic AMP system. Several explanations have been proposed to account for these results¹⁷⁻¹⁹. The consistency of our findings in the adenomas examined suggests that the effect of DA on adenylate cyclase is not due to a fortuitous association with a tumoral clone, but that it might be a physiological characteristic of all PRL-secreting cells. In the normal anterior pituitary the effect of DA on mammotroph adenylate cyclase might go undetected, because basal adenylate cyclase activity is contributed primarily by other cell types. Furthermore, the inhibitory coupling between DA and adenylate cyclase might be more pronounced in tumour cells. In fact, clinical data suggest the existence of a defective dopaminergic control of the pituitary in hyperprolactinaemic patients with adenomas¹³, and this might lead to supersensitivity of DA receptors in adenomatous cells²⁰.

Fig. 2 Effect of drugs on adenylate cyclase activity in homogenates of human PRL adenomas. *a*, Effect of various concentrations of DA in the absence (●) and presence (○) of 0.1 μ M trifluoperazine (Maggioli) (case 3). *b*, Effect of various concentrations of DA (●) and (-)-noradrenaline (▲) (case 5). *c*, Effect of various concentrations of the dopaminergic ergot CH-29-717 (Sandoz) (case 5). See legend to Table 1 for experimental details. Values represent the mean $\pm$ s.e.m. of at least three replicate samples.

Table 2 Case 7: the stimulation of adenylate cyclase by fluphenazine is competitively counteracted by DA

Addition	Cyclic AMP formed (pmol per mg protein per 8 min)
Control	65.84 ± 3.58
Fluphenazine 0.1 µM	82.32 ± 2.72*
Fluphenazine 0.1 µM + DA 10 ⁻⁶ M	77.21 ± 2.66
Fluphenazine 0.1 µM + DA 10 ⁻⁵ M	70.20 ± 1.75
Fluphenazine 0.1 µM + DA 10 ⁻⁴ M	66.24 ± 3.59
Fluphenazine 0.1 µM + DA 10 ⁻³ M	64.78 ± 1.79†

See legend to Table 1 for experimental details. Values represent the mean ± s.e.m. of at least three replicate samples.

* $P < 0.005$ relative to control; † not significant relative to control and $P < 0.001$ relative to fluphenazine (Squibb) 0.1 µM.

Note that at another site where pharmacological evidence indicates the existence of D-2 DA receptors, such as on central dopaminergic terminals²¹⁻²³, cyclic AMP and DA produce opposite effects, the former being stimulatory and the latter inhibitory to the synthesis of the neurotransmitter²⁴⁻²⁶. This suggests that an inhibitory coupling with adenylate cyclase might be a more general property of D-2 DA receptors.

We thank Drs S. Nicosia and G. Tonon for suggestions, Drs G. Faglia and J. Meldolesi for discussions and encouragement, Dr A. Dolphin for critical reading of the manuscript and Dr M. Giovanelli for supplies of human pituitary tumours.

Dihydroergocryptine binding and α -adrenoreceptors in smooth muscle

DIHYDROERGOCRYPTINE is a potent antagonist of α -adrenoreceptors¹ that has recently been labelled to high specific radioactivity with tritium². ³H-DHEC was found to bind to a crude membrane preparation of rabbit uterus, and a portion of this binding was suppressible by phentolamine². The saturability, reversibility and structural and steric selectivity of this specific binding component suggested that it represents α -adrenoreceptors mediating uterine contractions³⁻⁴. In subsequent studies, ³H-DHEC was used to tentatively identify α -adrenoreceptors mediating various biological responses in several tissues⁵⁻¹⁰. The evidence for the identity of ³H-DHEC binding sites in tissue fragments with functional α -receptors in intact tissues is indirect, and is based on the demonstration of similar potencies of various ligands in suppressing ³H-DHEC binding and producing or inhibiting physiological responses. The absolute potency of particular ligands to suppress binding or affect the physiological response, often differs markedly. However, this could be due to changes in the properties of receptors caused by tissue disruption, or the different conditions in which potencies are determined. Therefore, the validity of the use of ³H-DHEC or other reversible ligands to label functionally relevant receptors must be tested in experiments where the above complications can be reduced or eliminated. We report here the use of an irreversible α -adrenoreceptor antagonist which provided a way to bridge the gap between physiological experiments measuring mechanical responses of an intact tissue and binding assays using membrane fragments. α -Receptors mediating contractions of isolated rabbit uterine strips were irreversibly blocked by phenoxybenzamine (POB), and ³H-DHEC binding was then measured in membranes prepared from these POB-treated and from untreated control strips. The results obtained dissociate phentolamine-suppressible ³H-DHEC binding and α -receptors mediating uterine contraction, but indicate that a fraction of the binding with low capacity and high affinity for DHEC, may represent true postsynaptic α -receptors.

Myometrial strips were prepared from uteri of immature New Zealand rabbits and were mounted in tissue baths containing de Jalon solution at 31 °C. Concentration-response curves for noradrenaline (NA) induced isometric contractions were determined before and after a 20-min exposure to various concentrations of POB. A crude membrane fraction was then prepared from the control and POB-treated strips to test the *in vitro* binding of ³H-DHEC.

POB irreversibly blocked the NA-induced contractions of uterine strips. As little as 10⁻¹⁰ M POB produced significant inhibition, and complete block was achieved by 3 × 10⁻⁸ M (Fig. 1). Spare receptors were not evident in the rabbit uterus, as the threshold blocking concentration of POB (10⁻¹⁰ M) significantly reduced the maximal response to NA. The high blocking potency of POB and the absence of spare α -receptors have also been observed in other smooth muscles^{11,12}. POB treatment of the intact strips significantly reduced the specific binding of ³H-DHEC (8 nM) as compared with the binding to

Fig. 1 Effects of phenoxybenzamine (POB) on noradrenaline (NA)-induced uterine contractions and on the specific binding of ^3H -DHEC to uterine membrane fragments. Suppression of the maximal contractile response to NA (■), suppression of specific ^3H -DHEC binding after incubation of POB with intact strips (Δ) or with membrane preparations (▲). Points and bars represent mean $\pm$ s.e. of triplicate determinations in 4–9 experiments. Uteri were removed, and the two horns separated and longitudinally halved. The strips were trimmed of fat and endometrial tissue, and suspended in tissue baths containing de Jalon solution (in mM: NaCl, 154; KCl, 5.6; CaCl₂, 0.3; NaHCO₃, 6.0; glucose, 2.8; pH 7.4) at 31 °C, gassed with 5% CO₂ in O₂. Isometric contractions were recorded by force-displacement transducers (Grass FTO3C) and a polygraph. Contractions were induced by single graded doses of (–)noradrenaline, after which all but one strip were exposed to various concentrations of POB for 20 min. After a 1-h washout period NA concentration–response curves were redetermined and corrected for any spontaneous change as tested in the strip not exposed to POB. After thorough washing with de Jalon solution for 90 min, the strips were dismantled and a crude membrane fraction was prepared³. The strips were minced and homogenised in ice-cold buffer (0.25 M sucrose, 1 mM MgCl₂, 5 mM Tris HCl, pH 7.4, at 25 °C) with a Brinkman polytron (4 $\times$ 6s bursts). The homogenate was filtered through gauze and centrifuged twice at 500g for 10 min at 4 °C. The pellet was discarded and the supernatant centrifuged at 27,000 g (10 min, 4 °C) and washed twice with incubation buffer (10 mM MgCl₂, 50 mM Tris HCl, pH 7.5 at 25 °C), in which the final pellet was resuspended at 3–4 mg ml^{–1} protein. The same method was used to obtain membranes from freshly removed uteri. Aliquots of such membrane preparations were incubated with POB at 25 °C for 12 min (ref. 3). The suspension was then diluted with 50 vol incubation buffer and centrifuged and washed twice at 27,000 g. A control aliquot was treated the same way except for the addition of POB. The binding of ^3H -DHEC (NEN, 27.3 Ci mmol^{–1}) to uterine membranes was assayed by a rapid filtration method³. Incubations were in polyallomer tubes at 25 °C for 15 min and binding was terminated by adding 2 ml of incubation buffer to the 150- μ l aliquots containing 8 nM ^3H -DHEC, and immediate filtering through Whatman GF/C glass fibre filters. The filters were washed for 15 s with 20 ml of the same solution at 25 °C. Specific binding is the difference between binding in the absence and presence of 10 μ M phentolamine, and it was 30–50% of total binding. Control membrane preparations bound 90.6 ± 10.5 fmol ^3H -DHEC per mg protein.

membranes prepared from control strips not exposed to POB. However, the concentration of POB needed to suppress ^3H -DHEC binding was approximately 50 times higher than that required to produce equivalent block of the mechanical response to NA (Fig. 1), and even 10^{-6} M POB did not completely suppress binding. As this discrepancy may have been due to diffusion barriers that limited the access of POB to receptors inside the intact tissue, in a group of experiments POB was incubated with uterine membranes rather than with intact strips. Preparation of the membranes from the freshly removed uteri, incubation with various concentrations of POB and the subsequent assay of ^3H -DHEC binding were as described by Williams and Lefkowitz⁴. Suppression of ^3H -DHEC binding by POB in these preparations was practically identical to the suppression observed after exposure of intact strips to POB (Fig. 1). The 40% decrease in ^3H -DHEC binding by 10^{-7} M POB is comparable to the 45% suppression observed in similar experiments by Williams and Lefkowitz⁴. These observations eliminate the possibility that the dissociation of the effects of POB on the physiological response and on ligand binding could have been due to diffusion barriers in the intact tissue or to breakdown of POB in the incubation medium⁴.

Differences between the results of binding studies and experiments with functioning tissues could also be related to the fact that the ionic composition and temperature of the media used are usually very different. As ^3H -DHEC binding in the present experiments and in earlier studies^{2–5} was tested in Tris buffer at 25 °C, we repeated the last group of experiments using de Jalon solution at 31 °C for the final resuspension of membranes before their incubation with POB and the assay of ^3H -DHEC binding. One-half of each membrane preparation was exposed for 20 min to 3×10^{-6} M POB, the lowest concentration that produced complete block of contractions in strips, and binding of various concentrations of ^3H -DHEC was then tested both in the control and in the POB-treated sample (Fig. 2). POB did not significantly alter specific ^3H -DHEC binding at higher concentrations of the labelled ligand, thus confirming dissociation of these binding sites from α -receptors mediating smooth muscle contraction. However, the same concentration of POB almost completely eliminated specific binding at low concentrations of ^3H -DHEC (≤ 3 nM), and there seems to be a break in the control binding curve at the same ^3H -DHEC concentration. These latter findings suggest that the low-capacity, high-affinity component of DHEC binding (Fig. 2) may

represent true smooth muscle α -receptors with a high sensitivity to blockade by POB.

This possibility was further tested in a 'receptor protection' experiment. Three strips obtained from the same uterus were mounted in tissue baths. After determination of NA concentration–response curves, one strip was exposed for 20 min to 3×10^{-8} M POB alone, the second was exposed to 3×10^{-8} M POB in the presence of 10^{-5} M phentolamine, and the third remained untreated as control. Retesting the effect of NA after repeated washing of the strips for 1 h showed no significant change in the control, complete block in the POB-treated strip and a reduction of the maximal NA contraction from 2.15 to 1.05 g in the strip exposed to both POB and phentolamine (50% protection). The specific binding of ^3H -DHEC (2 nM) in membranes from the same three strips was 40.2, 0 and 22.1 fmol per mg protein, respectively, indicating 55% protection in the last preparation. In two other experiments, methoxamine-induced contractions of strips and suppression of ^3H -DHEC (2 nM) binding in membranes were tested in preparations obtained from the same uterus. Methoxamine was used as agonist, because it is not a substrate for monoamine oxidase, catechol-O-methyl transferase or neuronal uptake¹³ and, in the absence of spare α -receptors in the uterus, its EC₅₀ should be similar to its K_d. The observed mean EC₅₀ of 1.5×10^{-6} M for contraction and K_d of 5×10^{-7} M for binding are in good agreement.

The good correlation between irreversible block of the physiological response and suppression of ^3H -DHEC binding by POB, the similar degree of protection against both effects by phentolamine, and the similar absolute potency of methoxamine for contraction and binding suggest that the high-affinity component of ^3H -DHEC binding does, in fact, represent functional α -receptors in smooth muscle. For the first time, ligand binding and receptor-mediated mechanical responses were determined in the same preparation and could be directly compared. The second, high-capacity, binding component does not represent α -receptors mediating uterine contraction and the present results provide no information about the possible physiological role of these more numerous sites. They may be non-functional 'silent receptors' (ref. 14) for catecholamines, which may have affinities for various adrenergic ligands that are similar but not identical to the affinity of true receptors. Alternatively, the second binding component may be related to release-modulating α -receptors. POB is considerably more

Fig. 2 The effect of phenoxybenzamine on the specific binding of various concentrations of ^3H -DHEC to uterine membranes. Membranes were prepared from freshly removed uteri as described in the legend to Fig. 1, except that final resuspension of membranes before incubation with POB (3×10^{-6} M, 20 min, 31°C) and the binding assay (15 min, 31°C) was in de Jalon solution. Points are means $\pm$ s.e. of triplicate determinations from 4–7 different uteri. POB-treated ($\circ$) and control ($\bullet$) values are matched and membrane material from any one uterus was sufficient to test binding at 4–6 concentrations of ^3H -DHEC. In individual preparations, where at least four points were obtained at or below 3 nM ^3H -DHEC, Scatchard plots of such control values gave a mean K_d of 1.5 ± 0.4 nM and a b_{max} of $36.6 \pm \text{fmol per mg protein}$. In membrane preparations where most points tested were above 3 nM, the K_d of ^3H -DHEC binding was 5.5 ± 1.7 nM and the b_{max} was 97.3 ± 18.8 fmol per mg protein. (1, 2, 4, 8, 16 nM.)

* Indicates significant difference ($P < 0.005$) from the corresponding control value.

potent in blocking post- than presynaptic α -receptor responses¹², and the unexplained high potency of clonidine (K_d 0.23 μM) in suppressing the binding of 8 nM ^3H -DHEC in an earlier study³ is also compatible with the involvement of presynaptic receptors. However, more direct evidence is needed to decide this issue.

The present results should caution against prematurely equating ligand binding sites characterised *in vitro* with receptors subserving a well defined physiological function *in vivo*. ^3H -DHEC binding described in earlier studies in uterine^{2,4} or vascular smooth muscle⁵ differed from the high-affinity binding component in the present experiments: the K_d of ^3H -DHEC was 8–10 nM, and only high concentrations of POB suppressed specific binding⁴. This indicates that the sites involved were not smooth muscle α -receptors mediating contraction. Changes in the density of such ^3H -DHEC binding sites in oestrogen- and progesterone-treated rabbit uterus¹⁵ have been suggested to contribute to or explain the reciprocal change in α - and β -receptor-mediated mechanical responses of such preparations. As the binding sites detected are unrelated to smooth muscle α -receptors, the physiological significance of changes in their density remains to be established.

Substance P inhibits nicotinic activation of chromaffin cells

THERE is much interest in the possibility that substance P acts as a neurotransmitter and/or a neuromodulator at certain sites in the central and peripheral nervous system (for reviews see refs 1, 2). Although both excitatory^{3–6} and inhibitory^{6,9–11} actions have been observed *in vivo* and *in vitro*, the cellular mechanism of action of substance P has not been defined. Recent electrophysiological studies in the cat^{9–11} have provided evidence that substance P selectively depresses the nicotinic excitation of Renshaw cells by microiontophoretic application of acetylcholine (ACh). We show here that substance P inhibits the ACh-induced nicotinic response of adrenal chromaffin cells in culture to release ^3H -noradrenaline.

Intact and functional chromaffin cells were isolated from bovine adrenal glands by retrograde perfusion of the dissected medullae with collagenase (type 1, Sigma) in a Locke's buffer (pH 7.0) and purified by density gradient centrifugation on

Fig. 1 Inhibition by substance P (10^{-4} – 10^{-12} M; Beckman) of the release of ^3H -noradrenaline from cultured bovine adrenal medullary cells evoked by ACh (5×10^{-5} M). The percentage of the total cellular ^3H -noradrenaline released by 5×10^{-5} M ACh in the absence of substance P is shown on the ordinate. The results of a typical experiment are shown, where each point represents the release from a single, separate culture dish.

Table 1 Effect of substance P (SP) and Ca^{2+} on the release of ^3H -noradrenaline from cultured adrenal chromaffin cells

Secretagogue	Addition	% Intracellular ^3H -noradrenaline released mean $\pm$ s.d. (n)
5×10^{-5} M ACh	2.2 mM Ca^{2+}	20.9 $\pm$ 3.1 (47)
	5×10^{-5} M SP + 2.2 mM Ca^{2+}	3.9 $\pm$ 1.3 (5)
	No Ca^{2+}	1.8 $\pm$ 0.4 (3)
	1 mM EGTA	0.9 $\pm$ 0.1 (3)
5×10^{-6} M nicotine	2.2 mM Ca^{2+}	16.8 $\pm$ 2.4 (5)
	5×10^{-5} M SP + 2.2 mM Ca^{2+}	2.1 $\pm$ 0.4 (3)
	2.2 mM Ca^{2+}	15.3 $\pm$ 1.5 (7)
	5×10^{-5} M SP + 2.2 mM Ca^{2+}	15.1 $\pm$ 0.9 (2)
56 mM K^+	2.2 mM Ca^{2+}	2.3 $\pm$ 0.2 (3)
	No Ca^{2+}	2.3 $\pm$ 0.2 (3)

Percoll as described previously¹²⁻¹⁴. The purified cells were plated on collagen-coated plastic dishes (Corning 35 mm, 10^6 cells per plate) in Dulbecco's modified Eagle's medium (DMEM; Gibco), pH 7.2, in conditions shown to favour sympathetic neurite outgrowth in culture¹⁵. The cells attached firmly within 3 h, and by 8 h had extended processes with growth cones which eventually made contacts with other cells^{13,16}. The cells and their varicose processes contained high concentrations of catecholamines, as demonstrated by the glyoxylic^{14,17} and formaldehyde-glutaraldehyde^{14,18} fluorescence histochemical methods. By day 4 in culture they exhibited many of the morphological features of noradrenergic neurones in culture.

The pharmacological experiments were carried out on chromaffin cells after 4 and 5 days in culture. The plates were loaded for 2 h at 37 °C with ^3H -noradrenaline as described by Greene and Rein¹⁹ for sympathetic nerve cultures. In this technique any unbound amines and metabolites are washed out in a subsequent 2 h period and the washout medium replaced with HEPES-buffered Krebs-Ringer saline (KRH) for 15 min²⁰; however, instead of the 2.6 mM Ca^{2+} concentration used by Greene and Rein we used 2.2 mM Ca^{2+} as our previous work¹² has shown this concentration to effect maximum stimulation of ACh-induced catecholamine release from isolated adrenal medullary cells. After this adaptation period, the plates were incubated in KRH (5 min); KRH containing nicotinic and muscarinic agonists and/or antagonists (5 min); and KRH alone (5 min). Substance P, when tested, was present during the first two 5-min incubation periods. The radioactivity in each of the three incubation media and that remaining in the cells was determined as described by Greene and Rein¹⁹ using a Nuclear Chicago Isocap 300 scintillation counter, with external standards ratio. The results are expressed as the amount of ^3H -noradrenaline released in the 5-min stimulation sample expressed as a percentage of the total radioactivity originally present in the cells.

Pharmacological studies with nicotinic (nicotine, ACh) and muscarinic (methacholine) agonists and their antagonists (mecamylamine HCl; hexamethonium and atropine, respectively) showed that the adrenal chromaffin cells contained only nicotinic receptors. Methacholine (10^{-10} – 10^{-4} M), a muscarinic agonist, did not stimulate the cells to release ^3H -noradrenaline, and the ACh-induced release of ^3H -noradrenaline (ED_{50} 5×10^{-5} M) was not inhibited by low concentrations (10^{-5} – 10^{-10} M) of atropine. By contrast, substance P produced a dose-dependent inhibition of ACh (5×10^{-5} M) stimulated ^3H -noradrenaline release (Fig. 1) in the range 10^{-8} – 5×10^{-5} M, with an ID_{50} of approximately 5×10^{-7} M.

A similar inhibition of noradrenaline release by substance P was obtained when nicotine (5×10^{-6} M) was used as the agonist, but not when K^+ (56 mM) was used to depolarise the cells (Table 1). Omission of Ca^{2+} reduced the release induced by 5×10^{-5} M ACh and by 56 mM K^+ to 1.8% and 2.3%, respectively, of the total intracellular ^3H -noradrenaline, and addition of EDTA (1 mM) or EGTA (1 mM) reduced it to the basal

release level of 0.9% (Table 1). Substance P (5×10^{-5} – 10^{-10} M) by itself did not have a significant effect on the basal release rate of ^3H -noradrenaline from these cells in the presence of 2.2 mM Ca^{2+} .

As pharmacological studies have shown that isolated chromaffin cells^{12,21,22} contain only nicotinic receptors, our present results provide the first direct evidence at a cellular level that substance P acts as an inhibitory modulator of the nicotinic ACh response. Taken with the earlier microiontophoretic studies *in vivo*⁹⁻¹¹, our results support a role for substance P as an inhibitory neuromodulator at nicotinic receptor sites in the nervous system²³.

Efficient induction of immediate tolerance to contact sensitivity by hapten-modified spleen cells requires Ia⁺ cells compatible with recipient

IMMUNOLOGICAL distinction between 'self' and 'non-self' is important in maintaining normal homeostasis: a breakdown in this regulation probably results in auto-destructive processes. Recent developments in cellular immunology have shown that the induction of an immune response (sensitisation) involves the recognition of antigen in combination with products of the major histocompatibility complex (MHC)^{1,2}. In this context, it is pertinent to ask whether the induction and maintenance of specific immunological unresponsiveness (tolerance) to foreign antigens is also under genetic control. Contact sensitivity and tolerance to simple chemical compounds (haptens) in mice has provided insight into the complex cellular interactions involved in the unresponsive state³⁻⁵. Parenteral injection of the reactive

Table 1 Efficient induction of immediate tolerance to contact sensitivity of DNFB-modified spleen cells requires Ia-bearing cells

Treatment of DNP-SC tolerogen	DNFB sensitisation	DNFB challenge	Ear swelling (inches $\times 10^{-3}$) $\pm$ s.e.m.	% Tolerance
—	+	+	79.2 $\pm$ 3.7	0
NMS + C	+	+	25.8 $\pm$ 3.3*	71
Anti-Ia + C	+	+	59.5 $\pm$ 4.8*	26
—	—	+	3.6 $\pm$ 1.5	—

CBA/J erythrocyte-free spleen cell suspensions were prepared in Hank's balanced salt solution (HBSS). The cells were resuspended to 10^8 cells per ml in HBSS and either NMS or anti-Ia (A.TH into A.TL) antisera added at a concentration of 0.1 ml per 10^8 cells followed by incubation on ice for 60 min. Rabbit complement was then added and the suspension incubated at 37 °C for 30 min. Dead cells were removed by Ficoll-Isopaque gradient centrifugation⁹. Living cells were collected, labelled with DNFB as previously described⁴, and 3×10^6 DNP-SC injected on day 1 intravenously into age-matched CBA/J recipients. The recipient animals were sensitised with either 0.5% DNFB in acetone: olive oil (4:1 v/v) or acetone: olive oil (negative control) on days 0 and 1. On day 5, the recipients were ear challenged with 0.2% DNFB and swelling measured 24 h later. The values represent the mean 24-h ear swelling (4 members per group) $\pm$ s.e.m. The amount of tolerance obtained was calculated by comparing the response of each experimental group to that of positive (sensitised and ear challenged) and negative (ear challenged only) control groups: % Tolerance = [(positive - experimental)/(positive - negative)] $\times$ 100%.

* $P < 0.001$.

haptens 1-fluoro-2,4-dinitrobenzene (DNFB) or its sulphonate (DNBS) before epicutaneous sensitisation with DNFB results in unresponsiveness^{3,4}. This process seems to be mediated by at least two mechanisms, clonal inhibition and induction of suppressor T cells (T_s)⁶, both of which can be induced by either DNBS or DNFB coupled *in vitro* to red blood cells (DNP-RBC). The maximum tolerant state then develops 4–7 d after injection. However, another tolerogen, DNFB coupled *in vitro* to spleen cells (DNP-SC), produces maximum unresponsiveness immediately. This rapid induction of unresponsiveness was shown to be independent of T_s and thus was referred to as clonal inhibition⁶. The dichotomy between syngeneic DNP-SC and DNP-RBC in their ability to tolerate immediately was first thought to be due to either different homing characteristics or cell surface components⁴. With respect to the latter, an intriguing difference between the two tolerogens is the lack of I-region associated (Ia) antigens (of the MHC) on the surface of red blood cells^{7,8}. We have investigated this difference by tolerising mice with DNP-SC depleted of Ia⁺ cells or with DNP-SC from donors which are I-region incompatible with respect to the recipient animal. The results reported here indicate that the induction of immediate tolerance requires I-region compatibility between the donor of the DNP-SC tolerogen and the recipient.

Mice were tolerised with DNP-SC pretreated with either normal mouse serum (NMS) or anti-Ia antiserum plus rabbit complement. After the serum treatment and before labelling

with DNFB, dead cells were removed by differential centrifugation in Ficoll-Isopaque gradients⁹. One day after tolerisation the recipient mice plus appropriate controls were sensitised by two paintings with DNFB. All animals were ear challenged 5 d later and ear swelling measured 24 h later. The results are shown in Table 1. DNP-SC treated with NMS induced 71% tolerance. In contrast, DNP-SC which had been depleted of Ia⁺ cells induced only 26% tolerance, which is equivalent to the amount of unresponsiveness induced by another Ia-negative population of cells, DNP-RBC⁴. This decrease in tolerogenicity of DNP-SC depleted of Ia⁺ cells indicated that Ia⁺ cells are required to produce efficient immediate tolerance.

Further experiments were then done using the proper congenic strains to ascertain whether or not the Ia antigens of the tolerogen had to be identical with the recipient. For this analysis, it is necessary to keep K and D ends of the MHC compatible between the two so as to minimise any allogeneic effects. As seen in Table 2, when the tolerogen was incompatible with the recipient at the I region (DNP-A.TL into A.TH), there was no immediate induction of tolerance (0%) as compared to a syngeneic tolerogen (DNP-A.TH into A.TH), which produced immediate tolerance (53%). These results indicate that if the tolerogen and recipient share identical K and D regions, then I-region compatibility is required to induce efficient immediate tolerance.

The ability to induce unresponsiveness rapidly was also shown in the picryl chloride (Picl) system to depend on the cell population which was haptenated with picryl sulphonic acid (PSA) *in vitro*⁵. Whereas hapten-coupled spleen and lymph node cells were highly efficient at inhibiting contact sensitivity to Picl, PSA coupled to erythrocytes and thymocytes were ineffective. As the latter populations are thought to be deficient in Ia antigens^{7,8}, these results support the idea that induction of immediate tolerance requires hapten on Ia-compatible cells.

It must be pointed out, however, that the requirement for Ia-bearing cells is not seen when the sensitisation regimen is delayed. Miller and H.N.C.⁴ could not detect any differences between several haptenated cell populations (spleen, lymph node, peritoneal exudate cells and thymus) in their ability to induce tolerance to DNFB if the animals were tolerised 7 d before sensitisation. A possible explanation for this apparent inconsistency would be that host reprocessing has occurred during the longer time interval, such that the tolerogen is now expressed on the proper MHC background.

Host processing might also explain the observation that completely allogeneic DNFB-labelled cells (that is, K, D and I region incompatible) are as efficient as a syngeneic tolerogen in their ability to induce tolerance¹⁰. It is possible that alloreactivity might accelerate or somehow alter normal host processing, thereby allowing re-expression of the tolerogen on a self-MHC background. Therefore, I-region compatibility between the DNP-SC donor and the recipient is not required when K and D regions are different.

It is unlikely that the tolerant state induced here by DNP-SC is due solely to the production of a significant number of T_s because of the rapidity with which the unresponsiveness develops^{4,6}. Further evidence for the delay in the development

Table 2 Efficient induction of immediate tolerance to contact sensitivity by DNFB-modified spleen cells requires I-region compatibility between the tolerogen and recipient

Donor of DNP-SC tolerogen (KID)	DNFB sensitisation	DNFB challenge	24-h ear swelling (inches $\times 10^{-4}$) $\pm$ s.e.m.	% Tolerance	MHC compatibility between tolerogen and recipient
—	+	+	60.0 $\pm$ 3.8	0	—
A.TH (asd)	+	+	35.2 $\pm$ 2.0*	53	KID
A.TL (skd)	+	+	60.7 $\pm$ 2.9*	0	KD
—	—	+	13.3 $\pm$ 3.1	—	—

Donor spleen cells were prepared and labelled as described in Table 1. 3×10^6 DNP-SC were injected intravenously into A.TH recipients. The recipients were then sensitised and challenged as in Table 1.

* $P < 0.001$.

of T, is the fact that immune lymph node cells are not inhibited when transferred into animals tolerised 1 d previously with DNP-SC⁶. Also, cyclophosphamide pretreatment (which eliminates T_H precursors) does not alter the kinetics of immediate tolerance induction⁶. Therefore, we believe that DNP-SC is immediately inducing clonal inhibition. The tolerogen may act by blocking or inhibiting the T-cell receptors, thus preventing expansion of the specific clones after antigenic stimulation.

The exact role of Ia-bearing cells in the induction of immediate tolerance is unclear. However, one interpretation is that some T-cell clones which are required for the development of contact sensitivity may recognise DNFB in association with I-region gene products. Other investigators have reported that T cells recognise antigen plus surface MHC structures in both the induction and/or elicitation of immune responses, including delayed hypersensitivity¹¹, T-cell-B-cell collaboration¹², cytotoxic T-cell killing of virus-infected¹³ or hapten-modified target cells¹⁴, and T-cell proliferation *in vitro*^{1,2}.

The above mentioned studies indicate that the presentation of antigen in association with macrophage Ia determinants activates the T cell. In contrast, our results suggest that perhaps antigen, in association with an Ia-bearing cell, is capable of tolerising T cells. Thus, the decision for either tolerance or immunity depends not only on the nature of the ligands presented (antigen with Ia) but also on either their pathway of presentation (perhaps the tolerogenic action of DNP with Ia⁺ cells is due to the fact that it is not presented on macrophages) or their delivery with or without a second signal. This second signal would be required to activate the T cell; in its absence, tolerance results¹⁵.

It should be noted, however, that the relationship between hapten and Ia determinants has not been completely resolved. The hapten PSA has been shown to derivitise murine H-2 antigens *in vitro*¹⁶ but not the Ia-like structure in strain 13 guinea pigs¹⁷. Therefore, although both the hapten and Ia are required in immediate tolerance induction, the hapten may not be covalently attached to Ia but rather associated with some other structure on the Ia⁺ cells. In this case, the interaction is between the hapten-bearing cell and the target cell. Further experiments are underway to determine the exact role of Ia in the induction of immediate tolerance.

Serum amyloid P-component is an acute-phase reactant in the mouse

THE acute-phase reaction in mammals is characterised by an increase in the concentration of certain plasma proteins which starts within hours or days of most forms of acute tissue damage or inflammation, and persists with chronic inflammation and malignant neoplasia¹⁻⁴. Among acute-phase reactants are protease inhibitors, coagulation factors, complement components and transport proteins as well as proteins without known *in vivo* roles, such as the classical reactant, C-reactive protein (CRP)¹⁻⁴. The pathophysiological significance of the acute-phase reaction is not known, but it is a usual accompaniment of tissue damage, and it is of clinical value in the assessment of disease activity⁴. We now report that in the mouse, serum amyloid P-component (protein SAP)⁵, which is a stable plasma protein in man⁶, is a major acute-phase reactant. In addition, our observations facilitate investigation of the function of protein SAP and of the pathogenesis of amyloidosis, which is a serious disease in man.

Mouse SAP was isolated in different experiments from normal serum, acute phase serum following croton oil injection and ascitic fluid induced either by repeated intraperitoneal injection of Freund's complete adjuvant or by growth of the lymphocytoma McPc 1748 (ref. 7). Mouse CRP was isolated from the same acute-phase sera and ascitic fluids. The isolation procedures were those previously described for the human counterparts^{8,9} and are detailed specifically for the murine proteins elsewhere¹⁰. The SAP from the different sources was indistinguishable. Its behaviour on gel filtration was comparable to that of human SAP¹⁰, and it was homogeneous in gradient

Fig. 1 Effect of acute inflammation on murine serum levels of protein SAP. *a*, Subcutaneous injection of 0.2 ml of a 1% croton oil in liquid paraffin, *b*, intraperitoneal injection of 100 µg of *S. enteritidis* lipopolysaccharide W (Difco). Solid lines, CBA/Lac mice, broken lines, C57BL/6 mice; ○, males; ●, females. There were 5 mice in each group and the values shown are the arithmetic means of all animals tested individually in each group. Standard deviations are not plotted but the coefficient of variation was generally <10% except at the peak values when it was 15-25% in all groups.

polyacrylamide gel electrophoresis (PAGE) and reduced SDS-PAGE¹⁰, with a single subunit of molecular weight 25,300 (ref. 11). In the electron microscope mouse SAP was seen as pentameric disks, 8 nm in diameter, with a tendency to interact in pairs face-to-face (E. A. Munn, A. Feinstein and M.B.P., unpublished observations); this closely resembles human SAP⁹. Amino-terminal analysis revealed a blocked N terminal (C. Milstein, A. Feinstein and M.B.P., unpublished observations). These features, and the serum concentrations reported below, distinguish mouse SAP from serum amyloid A (SAA) and other known proteins.

Immunisation with the isolated SAP induced a monospecific rabbit antiserum which was used in an electroimmunoassay¹² of serum SAP calibrated with the pure protein. Murine serum CRP was measured by electroimmunoassay using a monospecific sheep anti-human CRP which cross-reacted with mouse CRP; isolated mouse CRP served as the standard.

Fig. 2 Effect of *S. mansoni* infection on serum levels of protein SAP in male CBA/Lac mice. Each point represents the arithmetic mean with 1 s.d. of 6 animals in each group. Solid lines, mice infected percutaneously with 20 cercariae¹³ on day 0; broken lines, non-infected age-matched controls.

SAP concentrations rose four- to six-fold in the sera of CBA mice and up to 50-fold in C57BL/Cbi mice within 24–48 h of injection of *Salmonella enteritidis* lipopolysaccharide W (LPS) or croton oil (Fig. 1). On day 32 after the injections, the levels were at pretreatment values in the LPS experiment but were still elevated in the mice given croton oil (100 µg ml⁻¹ in CBA, 10–20 µg ml⁻¹ in C57BL/Cbi mice). Forty days after infection of CBA mice with cercariae of *Schistosoma mansoni*¹³ the serum levels rose sharply and remained elevated (Fig. 2). This coincides with the time of incidence of granulomatous inflammation in the liver. Mice which had received implants of isogenic or xenogenic tumours also had raised serum SAP concentrations (Fig. 3).

The elevation of murine SAP levels after both acute stimuli and more protracted events, such as parasitic infestation and tumour growth, differs from the behaviour of SAP in man. The normal human serum level of SAP is 30–40 µg ml⁻¹; it does not alter significantly after major surgery and is only slightly increased during chronic active diseases⁶. On the other hand, the level of human CRP in disease ranges up to 600 µg ml⁻¹ (refs 6, 14), whereas, although the mouse CRP concentration rose in the present experiments, it did not exceed 2 µg ml⁻¹. These data agree with the results of a new fluorimetric immunoassay for CRP¹⁵. In man, CRP and SAP share substantial homologies of amino acid sequence, similar subunit composition and comparable appearance in the electron microscope¹⁶, and they both undergo calcium-dependent ligand binding^{8,9}. However, the specific interaction of CRP with pneumococcal C-polysaccharide⁸ and of SAP with agarose⁹ has been used to isolate

them in pure form, and also to identify very similar proteins in the sera of fish, amphibia, birds and non-primate mammals¹¹. These proteins from lower animals share amino acid sequence homologies with their human counterparts and each other (C. Milstein, A. Feinstein and M.B.P., unpublished observations). The acute-phase behaviour of murine SAP suggests that there may also be a functional overlap between CRP and SAP in different species.

The consistent differences in serum level of protein SAP observed in healthy adult CBA and C57BL/Cbi mice before acute-phase stimulation (Fig. 1) were confirmed in animals of the same strains bred and housed in other institutions. Sera from other healthy normal mice showed a consistent pattern of interstrain variation over a 50-fold range (Fig. 4). F₁ hybrids of high (DBA/2) and low SAP (C57BL/6) strains bred in two different institutions had low SAP levels. Outbred nude (athymic) mice and T-deprived CBA/Lac mice¹⁷ had levels comparable with those of intact animals (Fig. 4), suggesting that T-dependent immunocompetence is not required for maintenance of normal levels. The commensal flora are also not essential, as serum SAP concentration was not significantly different in conventional and germ-free CBA/Lac mice (Fig. 4). The observed strain variation suggests a genetic influence on SAP production but it remains to be established whether this is a direct primary effect on the protein synthetic and/or catabolic rates or whether it is secondary to hereditary influences on susceptibility to prevalent acute-phase stimuli such as microbial infection or physical factors.

The normal role of protein SAP *in vivo* is not known, but this protein is a minor constituent of amyloid deposits¹⁸ both in man and in experimental animals. We have recently observed sustained elevation of the serum SAP level during induction of amyloidosis in mice¹⁹, suggesting that it may have pathogenetic significance.

Fig. 3 Effect of tumour implantation on murine serum levels of protein SAP. C, control non-implanted mice; Ea, Ehrlich's ascites tumour, 5 d post-implantation; RiL, radiation-induced leukaemia, 6 d post-implantation; A3, human astrocytoma grade III, 6 d post-implantation; A4, human astrocytoma grade IV, 3 months post-implantation; T-CBA/Lac, T-deprived CBA/Lac mice¹⁷.

T antigen is bound to a host protein in SV40-transformed cells

THE early region of the small DNA tumour virus, simian virus 40 (SV40), is known to code for at least two polypeptides, the t and T antigens ('small t' and 'large T'). Both these polypeptides are expressed in cells transformed by the virus¹⁻⁴, and the T antigen has been shown to be essential for both the initiation and maintenance of the transformed state⁵⁻⁹. We therefore need to know how this T protein interacts with components of the host cell in order to understand the mechanism of SV40-induced transformation. We report here that the T antigen in a line of SV40-transformed mouse cells forms an oligomeric complex with a specific cell coded protein.

When an extract of the SV40-transformed mouse cell line SVA31E7 is immunoprecipitated by as little as 1 µl of a rabbit antiserum raised against purified T (ref. 10), two polypeptides are clearly specifically immunoprecipitated (Fig. 1, tracks 0, 1). The most slowly migrating species has a molecular weight of 94,000 and is identical to the T antigen precipitated from extracts of SV40 lytically infected monkey cells^{10,11}. The faster migrating species has an approximate MW of 53,000 (53 K) and has not been detected in SV40 lytically infected monkey cells. These same two polypeptides were also specifically immunoprecipitated by other anti-T sera: hamster anti-T sera (raised by inoculating the animals with the SV40-transformed hamster cell line, H65), mouse anti-T sera (raised by repeatedly immunising BALB/c mice with the SV40-transformed mouse cell line, SVT2 (ref. 12)), and anti-U sera, which were raised in monkeys and are specific for the C-terminal end of T (refs 13,14).

Fig. 1 Quantitation of T and 53K immunoprecipitation by rabbit anti-T serum. An equivalent aliquot of an NP40 cell extract of ³⁵S-methionine-labelled SVA31E7 cells was added to each of 6 tubes followed by normal rabbit serum and rabbit anti-T serum in the following respective amounts: track 0, 30 µl, 0 µl; track 1, 29 µl, 1 µl; track 3, 27 µl, 3 µl; track 10, 20 µl, 10 µl; track 30, 0 µl, 30 µl; track 100, 0 µl, 100 µl. After 3 h incubation at 4 °C, 100 µl of a 10% suspension of fixed *Staphylococcus aureus*²⁰ was added to each tube and following a further 10 min incubation the bacteria were washed 3 times in NET buffer²⁰ and collected by centrifugation. Bound proteins were eluted in 55 µl of sample buffer and 10 µl of each eluate loaded on a 7-20% linear gradient acrylamide gel. The dried gel was autoradiographed for 24 h.

The immunoprecipitation of the 53K protein by the rabbit anti-T serum has two possible explanations, either that the 53K protein shares common antigenic determinants with the gel-purified T antigen used to immunise the rabbit or that the protein is bound in a complex to another species that has such antigenic determinants. The 53K protein could then be specifically immunoprecipitated by the anti-T serum in a 'piggy-back' fashion, in the same way, for example, as antisera to human $\beta 2$ -microglobulin immunoprecipitate HLA antigen¹⁵.

Fig. 2 The strips of dried polyacrylamide gel containing the T antigen (●) and 53K protein (■) from each track were excised, using the autoradiograph as a template, from the gel shown in Fig. 1. Each strip was solubilised²¹ and counted. The c.p.m. present in each band in each track are plotted against the input of rabbit anti-T serum used to immunoprecipitate the cell extract.

To distinguish between these two possibilities we first quantitated the ability of the rabbit anti-T serum to immunoprecipitate the 53K protein, and the T antigen from an extract of SVA31E7 cells. The precipitation ratio for the two proteins (c.p.m. in T/c.p.m. in 53K) remained essentially constant over a 100-fold range of anti-T serum input (Figs 1, 2). Therefore, either the serum has a very similar titre against both species, that is, the 53K protein and T share the majority of the antigenic determinants recognised on T by this antiserum, or the 53K protein is being immunoprecipitated because it is bound to T.

Normal rabbit serum does not precipitate a detectable 53K band from untransformed mouse 3T3 A31 cells. This may be due to one or both of two reasons. Either the cells do not contain the 53K protein or, as there is no T with which it can complex, the 53K protein present is not precipitated by the rabbit antiserum specific for T. A similar experiment to that shown in Figs 1 and 2 with a lower input of cell extract showed that the ratio of T to 53K protein remained the same in serum excess.

It is known that the rabbit anti-T serum, which was raised against T antigen purified by SDS-polyacrylamide gel electrophoresis, recognises a set of determinants on T that are very stable, being resistant to heat, SDS and disulphide bond reduction (ref. 10 and D.P.L. and L.V.C., unpublished). Therefore, we used a direct binding radioimmunoassay to determine whether the isolated 53K protein possessed these antigenic determinants. The results of this assay (Fig. 3) indicate that 53K protein separated from T by SDS-gel electrophoresis is no longer precipitated by the rabbit anti-T serum, whereas the T antigen isolated in the same way is still fully reactive. This shows that the determinants recognised by the rabbit anti-T serum on T are absent from the 53K polypeptide. The immunoprecipitation of the 53K protein from cell extracts by this serum must therefore be due to the fact that it exists in a complex with T. Preliminary gel chromatography results are consistent with this

idea. T and the 53K protein eluted together from Sephacryl S-200 (exclusion limit 0.25×10^6) in the excluded volume (Fig. 4). Sucrose gradient analysis of extracts of transformed cells has shown that the 53K protein and a fraction of the T antigen sediment together at about 14–16S (F. McCormick, personal communication). Co-elution or co-sedimentation clearly do not prove that T and the 53K protein occur in the same complex but are consistent with the complex idea.

We then tested all the other sera which had immunoprecipitated T antigen and the 53K protein from the cell extract to see whether they could bind to the isolated 53K protein and T antigen. The anti-U serum and several different batches of hamster anti-T sera behaved like the rabbit anti-T polypeptide serum in that they efficiently re-immunoprecipitated the gel-purified T antigen but failed to bind the isolated 53K polypeptide. In contrast, the hyperimmune mouse anti-T serum specifically bound both the isolated 53K polypeptide and the T antigen (Fig. 3a, c). The binding of this mouse serum to the gel-purified T antigen from the SVA31E7 cells could be completely inhibited by an unlabelled extract of SV40-infected monkey cells but this treatment did not reduce its titre against

Fig. 3 Serum binding to purified polypeptides. Polypeptides for binding assays were purified from ³⁵S-methionine-labelled cell extracts by immunoprecipitation and SDS-polyacrylamide gel electrophoresis. Cells (PY6 or SVA31E7) were grown in 90-mm dishes in E4 medium with 10% calf serum, and labelled for 3 h with 500 µCi ³⁵S-methionine, then extracted in 0.5% NP40 Tris, pH 8.0, for 30 min on ice¹⁰. To the supernatant of the centrifuged extract, 100 µl of our hamster anti-T serum (for A31E7 cells) or 100 µl of mouse anti-T serum (for PY6 cells) was added. Three hours later 200 µl of *S. aureus* was added and the bacteria washed, collected and eluted as described for Fig. 1. The eluted proteins were separated on 15% polyacrylamide slab gels. The gel fragments containing the polypeptides of interest were located by autoradiography of the dried gel, excised with a scalpel and rehydrated in 2 ml of 0.1 M pH 9 bicarbonate buffer containing 0.1% SDS. Binding assays were carried out as described previously¹⁰ except that 50 µl of *S. aureus* was used in the final step. a, Binding to T polypeptide from A31E7 cells by: (1) 10 µl rabbit anti-T serum, (2) 10 µl normal rabbit serum, (3) 10 µl mouse anti-T serum, (4) 10 µl normal mouse serum. b, Binding assay control. Binding to a 42K protein from A31E7 cells which is nonspecifically precipitated from cell extracts. Sera as in a. c, Binding to 53K protein specifically precipitated from A31E7 cells by sera as in a. d, Binding to 52K protein, specifically precipitated from PY6 cells with mouse anti-T serum, by sera as in a. Ordinate is the % of input ³⁵S-labelled protein bound to *S. aureus*. Correction for counter background only.

the 53K protein. Its binding of the 53K protein was, however, inhibited by unlabelled extracts of the SV40-transformed mouse cell lines, SVT2 (the cell line used to immunise the mouse) and SVA31E7 (the cell line from which the purified 53K polypeptide was prepared). Therefore, both the 53K protein and T antigen have unique non-cross-reactive antigenic determinants and the mouse serum contains some antibodies specific for the 53K protein and some specific for T antigen.

This conclusion has been supported by the results of *in vitro* synthesis experiments carried out in collaboration with E.

Fig. 4 Gel chromatography of transformed cell extract. Cell extract from ^{35}S -methionine-labelled SVA31E7 cells (10^9 c.p.m.) was applied to a Sephacryl S-200 column ($1.5 \text{ cm} \times 34 \text{ cm}$) and eluted with buffer containing 0.1 M NaCl , 0.01 M Tris , $\text{pH } 8.0$, $1 \text{ mM dithiothreitol}$ and $5\% \text{ glycerol}$. One-ml fractions were collected and 0.1 ml of selected fractions immunoprecipitated with hamster anti-T serum. The immunoprecipitates were analysed by gel electrophoresis as described for Fig. 1. Each track is labelled with the fraction number, indicating the number of ml from addition of the sample to the column. The void volume of the column was estimated to be 20 ml . Much of the T antigen and 53K protein eluted around this position, whereas t was found around 35 ml and the $42,000$ band, thought to be actin, at around 28 ml .

Paucha. When polyadenylated mRNA from SVA31E7 cells was translated in the mouse L-cell protein synthesising system, our hamster anti-T serum immunoprecipitated the T and t polypeptides but not the 53K protein, whereas this same serum could immunoprecipitate both T and the 53K protein from *in vivo* labelled cell extracts. This is not due to a failure to translate the mRNA coding for the 53K protein, as when the same *in vitro* product was immunoprecipitated by the mouse anti-T serum (which contains antibodies to the isolated 53K protein), the 53K protein could then be detected in addition to the T and t polypeptides. This indicates that the T antigen and 53K protein do not assemble to form a complex in the *in vitro* conditions used in the translation reaction.

We have only encountered one other batch of serum able to bind the isolated 53K protein from SVA31E7 cells. This serum was raised in hamsters by inoculation with TSV5 C12 hamster transformed cells. Such reactivity explains why P. May *et al.* (in preparation), in contrast to the previous results of E. Paucha (personal communication), have been able to detect the 53K protein in their cell-free translation of polyadenylated mRNA from SV40-transformed mouse cells.

We postulate that the 53K protein is not virally coded because (1) we could not detect it in lytically infected monkey cells, (2) it shares no detectable antigenic determinants with T, but does have its own set of antigenic determinants (immunogenic in syngeneic mice), and (3) the DNA sequence and mRNA map-

ping data indicate that it would be difficult for the early region of SV40 to encode a third polypeptide of $53,000 \text{ MW}^{16-18}$. If the protein is not coded for by the virus, then it might be detectable in cells transformed by other viruses, by radiation, by chemical carcinogens or even in untransformed cells. In these cases it would not be complexed to T antigen and would therefore be precipitated only by antibodies specific for the 53K protein itself but not by antibodies to T antigen. An initial study supports this idea. When extracts of the polyoma-transformed mouse cell line PY6 were immunoprecipitated with the rabbit anti-T serum, no specific band was detected; immunoprecipitation of the same extract with the mouse anti-T serum (which contains antibodies to the 53K protein) did specifically bring down a band of $\sim 52,000 \text{ MW}$. This cross-reactive protein, when isolated from the gel, was reprecipitated specifically by the mouse antiserum (Fig. 3d). Significantly, it was also specifically bound by the anti-TSV5 C12 serum but not by anti-U serum, rabbit anti-T polypeptide serum (Fig. 3d) or our hamster anti-T serum. The 52K protein from PY6 cells was always precipitated to a lesser extent than the 53K protein. For this reason we believe that the two proteins are related but not identical.

It will be necessary to establish further the nature of the 53K protein, but its specific binding to T antigen, and the presence of an antigenically related protein in polyoma-transformed cells imply that it may have a crucial role in the modulation of the transformed state. Thus, it is possible that it acts to neutralise some of the specific functions of T antigen; for example, it could render the cell non-permissive by preventing the T-dependent initiation of viral replication¹⁸ or it may normally act as a regulator of certain cellular functions related to growth control and itself be neutralised by binding to T antigen. It is of prime importance to determine the level of this T antigen binding protein in untransformed cells and normal tissues and to see if it is induced by other carcinogenic agents.

We thank Dr A. M. Lewis, Jr for the monkey anti-U serum, Dr P. May for the hamster anti-TSV5 C12 cell serum, and Drs P. May, E. Paucha and F. McCormick for permission to quote their unpublished results. PY6 and SVA31E7 cells were from Dr Y. Ito.

Note added in proof: The presence of a middle-T antigen species in SV40 transformed rat cells and SV40 transformed mouse cells has recently been reported²²⁻²⁴ and a preliminary characterisation of the protein carried out²⁵.

Persisting DNA synthesis in SV40-transformed cells in the presence of cycloheximide

INHIBITION of protein synthesis decreases the rate of DNA synthesis in both prokaryotes and eukaryotes. In prokaryotes, DNA synthesis is dependent on protein synthesis only for the initiation of replication¹. In the case of eukaryotes, reduction of DNA synthesis occurs rapidly after the inhibition of protein synthesis^{2,3}, although the mechanism of the tight coupling between protein and DNA synthesis is unclear. The DNA which is synthesised at a reduced rate in these conditions is basically normal except that the elongation step seems to be modified^{2,5}. Newly replicated DNA synthesised in the presence of cycloheximide seems to be associated with less chromatin protein, because chromatin synthesised in these conditions is more susceptible to digestion by DNases^{3,4}. T antigen of simian virus 40 (SV40) is a product of the A gene of the virus⁵ and has been shown to have a role in the establishment and maintenance of transformation⁶⁻⁹. There is evidence that T antigen is required for the initiation of viral DNA replication¹⁰ and the induction of synthesis of cell DNA¹¹⁻¹⁵. It has also been suggested that T antigen initiates DNA synthesis in transformed cells and thereby serves to retain those cells in the transformed state^{10,16-18}. Recently, T antigen was purified almost to homogeneity, and its microinjection into quiescent mouse cells induced DNA synthesis¹⁹. However, the mechanism of action of T antigen in cell DNA synthesis remains to be clarified²⁰. If T antigen acts on cellular DNA synthesis, SV40-transformed cells which contain T antigen may behave differently from other cell lines in their ability to continue DNA synthesis in conditions of protein synthesis inhibition. We report here that DNA synthesis in SV40-transformed cells continued at an almost normal rate while protein synthesis was inhibited by cycloheximide, whereas DNA synthesis in malignant tumour cells without T antigen did not continue in these conditions.

HeLa and SV80, the former derived from human cervical cancer and the latter a human cell line transformed by SV40²¹, were grown in Dulbecco's modified Eagle's medium (Nissui)

supplemented with fetal bovine serum 10% (Gibco) and streptomycin sulphate (200 µg ml⁻¹). Cells were usually cultured for 3-4 d and used when they had reached subconfluence. Evidence of mitosis was observed under the microscope, indicating active growth. Protein and DNA synthesis in the presence of various concentrations of cycloheximide were studied by measurement of the incorporation of radioactive precursors into acid-precipitable material in cells cultured on 13-mm cover slips. As seen in Table 1a, in both cell lines, protein synthesis was reduced by cycloheximide in a concentration-dependent manner. DNA synthesis in HeLa cells was inhibited in the presence of cycloheximide (Table 1b), which was consistent with observations of cycloheximide inhibition of DNA synthesis in eukaryotes¹⁸⁻²⁰. In SV80 cells, however, DNA synthesis was maintained at an almost normal rate in the presence of cycloheximide (Table 1b), although longer treatment of SV80 cells with cycloheximide reduced DNA synthesis gradually. The ³H-thymidine incorporated into cells treated with or without cycloheximide was located in nuclei, was resistant to alkaline hydrolysis (0.3 M KOH at 37 °C for 18 h), and was completely solubilised by acid hydrolysis (10% perchloric acid at 100 °C for 15 min). This resistance of DNA synthesis to inhibition of protein synthesis was seen not only for SV80 cells, but also for such hamster cell lines transformed by SV40 as SVH93, CHLWT15 and CHLA239L1.

We then carried out experiments to determine whether protein fractions such as histones and/or other proteins which would be required for the maintenance of DNA synthesis were supplied at a normal rate in SV80 cells in the presence of cycloheximide. SV80 cells were labelled with ³H-leucine for 3 h in the presence or absence of cycloheximide. Radioactivity and protein content in cytoplasmic and nuclear fractions of the cells and acid-extractable and residual fractions in nuclei were determined. The acid-extractable fraction contained mostly histones, whereas the residual fraction showed no detectable histones when checked by SDS-polyacrylamide gel electrophoresis. Synthesis of proteins from cells treated with cycloheximide was inhibited to approximately 5% of control regardless of the fractions determined (Table 2). The fluorographic pattern of SDS-polyacrylamide gel electropherograms of cytoplasmic and nuclear proteins confirmed none of specific protein retained a normal rate of synthesis with cycloheximide treatment. In the presence of cycloheximide, DNA in newly

Cells were plated on 13-mm cover slips in a multiwell culture tray (Costar) with 1 ml of medium and cultured for 3-4 d until subconfluent. After 0.5, 1.5 or 2.5 h of cycloheximide addition, L-[4,5-³H]leucine (50.6 Ci mmol⁻¹, Amersham) was added at a final concentration of 13 µCi ml⁻¹ and cells were labelled for 1 h. Medium was discarded and the cells were washed twice with cold phosphate-buffered saline, four times with 10% cold trichloroacetic acid, and finally with ethanol. After drying, 10 ml of scintillation cocktail (4 g diphenylloxazole in 1 toluene) was added and radioactivity was counted. b, As in a except that [6-³H]thymidine (26.6 Ci mmol⁻¹, Amersham) was added at a final concentration of 13 µCi ml⁻¹.

† % Of control without cycloheximide.

Table 2 Inhibition of protein synthesis by cycloheximide

Fractions	Protein (mg)		Radioactivity (c.p.m. $\times 10^{-4}$)		Specific radioactivity (c.p.m. $\times 10^{-4}$ per mg)	
	Control	Cycloheximide	Control	Cycloheximide	Control	Cycloheximide
Whole cell	6.66	6.58	128.7	4.88	19.33	0.74(3.8)*
Cytoplasm	3.30	3.77	57.4	2.80	17.40	0.74(4.3)
Nuclei	1.50	1.50	47.2	2.03	31.44	1.35(4.3)
Acid extractable	1.28	0.76	10.0	0.30	7.89	0.39(5.0)
Residual	0.28	0.19	19.3	0.56	68.8	2.97(4.3)

SV80 cells were labelled with L-[4,5- ^3H]leucine for 3 h from 0.5 to 3.5 h after addition of $5.0 \mu\text{g ml}^{-1}$ of cycloheximide. Cells were then washed twice with phosphate-buffered saline, homogenised in reticulocyte standard buffer (10 mM Tris-HCl, pH 7.4; 10 mM NaCl; 1.5 mM MgCl_2), and spun down through a 0.88 M sucrose layer to pellet nuclei. Supernatant including sucrose cushion was saved as cytoplasmic fraction. Acid-extractable and residual proteins from nuclei were separated by the 0.25 M H_2SO_4 method²⁷. All fractions were pelleted and washed with 10% cold trichloroacetic acid, except for the acid-extractable fraction which was pelleted by adding 4 volumes of ethanol²⁷. Pellets were dissolved in 0.2 M NaOH. Radioactivity was measured after mixing with scintillation cocktail PCS (Amersham). Protein was assayed by the method of Lowry *et al.*²⁸.

* % Of control without cycloheximide.

synthesised chromatin of both SV80 and HeLa cells was more susceptible to digestion by micrococcal nuclease, as compared with that in control without cycloheximide, suggesting a reduced assembly of proteins into newly synthesised chromatin. These results indicated that DNA synthesis in SV80 cells continued at an almost normal rate under a reduced supply of new proteins in the presence of cycloheximide.

As inhibition of DNA synthesis by cycloheximide was reported to occur very rapidly, within a few minutes^{2,3}, certain proteins with a very short half life were assumed to be required for the maintenance of DNA synthesis, although isolation and characterisation of these proteins have been unsuccessful²². SV80 cells contained high amounts of T antigen among SV40-transformed cell lines²³. T antigen was located almost exclusively in nuclei²⁴ and was bound to double-stranded DNA²⁵ and chromatin²⁶. The fact that T antigen was required for the initiation of each round of viral DNA synthesis⁶ and the fact that the size of replicon units in SV40-transformed cells was smaller than that in normal cells¹⁸ suggested that T antigen may be involved in cell DNA synthesis. These and the following results seem to favour the idea that T antigen may maintain cellular DNA synthesis despite the absence of protein synthesis, directly or indirectly: (1) in all four SV40-transformed cell lines of human and rodent that we have tested, DNA synthesis continued in the presence of cycloheximide; (2) in cells transformed by the ΔTA mutant of SV40 virus, CHLA239L1, which contained temperature-sensitive T antigen, DNA synthesis continued at the permissive temperature, but was inhibited at the non-permissive temperature in the presence of cycloheximide; (3) variation in the resistance of DNA synthesis to inhibition of protein synthesis among SV40-transformed cell lines correlated with the concentration of T antigen in cells. It should be emphasised, however, that these results do not prove a direct action of T antigen on cell DNA synthesis, but may provide us with a new approach for the analysis of the function of T antigen in transformed cells.

We thank Drs K. Yoshino and R. Baserga for providing us with HeLa and SV80, respectively.

Sodium channels in rabbit cardiac Purkinje fibres

SODIUM channels are essential for normal impulse conduction in the heart and are a major target for the therapeutic action of antiarrhythmic drugs. However, these channels have not been well studied due to the difficulty of measuring cardiac sodium currents under voltage clamp. Previous efforts have not been generally accepted because of doubts about the adequacy of voltage control¹⁻⁴. The absence of direct information on cardiac sodium channels is unfortunate as evidence exists suggesting that they differ significantly from sodium channels in other excitable membranes. First, blockade of sodium-dependent impulses in heart requires tetrodotoxin (TTX) at 10^3 - 10^4 times greater concentrations than in nerve or skeletal muscle⁵. Second, the effect of TTX in heart appears to be voltage-dependent¹⁰, unlike its action on sodium currents in other excitable cells^{11,12}. These findings raise the possibility that cardiac sodium channels may have novel structural properties. Further progress depends on the development of reliable measures of sodium current in the heart itself. We report here voltage-clamp recordings of sodium currents in rabbit Purkinje fibres satisfying a number of criteria for adequate voltage control. The experiments indicate the feasibility of characterising sodium channels in an intact mammalian cardiac preparation and open the way for the direct analysis of antiarrhythmic drug action on cardiac conducting tissue.

Fig. 1 Sodium currents in the rabbit Purkinje fibre. Membrane currents elicited by depolarisations from a holding potential of -77 mV. Traces are the average of two sweeps (10 kHz filtering) and have been corrected for steady current by computer subtraction. (The size of the steady current is evident in Fig. 2.) Command pulses were exponentially lagged to allow higher clamp gain without ringing and to protect the preparation by limiting the initial surge of capacitive current. Cylindrical surface area, 0.0032 cm²; total capacity, 18 nF. Fibre T46-1, 0 Ca (5.4 mM Mn), 13 °C.

The experiments were carried out in rabbit Purkinje fibre preparations using the two-microelectrode voltage-clamp technique. Johnson *et al.*^{13,14} suggested the choice of the rabbit Purkinje fibres because of its structural advantages over other preparations. It lacks transverse tubules, unlike mammalian ventricular muscle, and it has wide (1 μ m) intercellular clefts, unlike sheep Purkinje fibres or frog myocardium. The absence of narrow or long extracellular spaces is important in avoiding undesirable external voltage drops. The structural features of the rabbit Purkinje fibre are consistent with its electrical properties. Shortened rabbit Purkinje fibres behave like simple, terminated RC cables, with an extremely low external series resistance to transmembrane current flow^{15,16}. In studying the rabbit Purkinje fibre, we avoided the double sucrose gap method used in earlier studies^{14,17} because of the reported poor viability of the preparations and the problem of extracellular shunt currents¹⁴. We chose instead the two-microelectrode method¹⁸, having found that it allows normal resting and action potentials to be recorded over periods up to several hours long^{15,16}. The main obstacle when studying I_{Na} is longitudinal nonuniformity; this was reduced to an acceptable level by using a low external sodium concentration (15 mM), and short preparations (450–700 μ m) to restrict the distance from the current passing electrode to either of the healed-over ends. Reduction of sodium conductance by TTX is less appropriate in these experiments because, as Baer *et al.* have suggested¹⁰, its inhibitory effect is voltage-dependent (T.J.C., C. J. Cohen and R.W.T., unpublished). Temporal resolution of I_{Na} was improved by cooling (13–23 °C). Interference from other ionic currents was not a serious problem as I_{Na} is much faster and larger than other

Table 1 Voltage-dependent inactivation of sodium current

Expt	Solution	Temperature (°C)	V_{test} (mV)	E_h (mV)	k (mV)
T42-3	5.4 Ca	22	-13	-72	5.45

Analysis of $h_{\infty}(E)$ as shown in Fig. 4. Sodium currents were measured at the test potential (V_{test}) indicated. E_h and k were evaluated for each experiment by fitting the data with equation (2).

components such as the slow inward current or delayed potassium current. These currents and twitch contraction were largely inhibited in most experiments by including manganese ion in the external solution. The composition of the external solution was as follows (mM): 15 NaCl, 135 choline-Cl (Mallinckrodt), 4 KCl, 0.5 MgCl₂, 10 Tris-buffer (pH 7.4), 5 glucose, and either 5.4 CaCl₂ or 1.8 CaCl₂ + 3.6 MnCl₂ or 5.4 MnCl₂. (See Table 1 and Figure legends for concentrations of Ca or Mn.) Records of membrane current and intracellular potential were taken with a PDP 8/e computer after low pass filtering at 10 kHz.

Figure 1 shows sodium currents (a) produced by step depolarisations from a holding potential at -77 mV (b). The traces in a show total membrane current (capacitive plus ionic) with a small component of steady current omitted. The depolarising step to -68 mV evokes an outward capacity transient but no significant time-dependent ionic current. Larger steps to -46 , -41 , -37 and -28 mV produce progressively greater surges of I_{Na} and progressively earlier peak current. The largest inward current is associated with the step to -28 mV. With further depolarisation, the transient current becomes smaller (-19 mV) and eventually reverses (-3 mV).

Fig. 2 Procedure for correcting current records for linear capacitive components. The current response to a subthreshold depolarisation to -59 mV was fitted by connecting the first six data points (1.8 ms) and fitting later points by a single exponential ($\tau = 1.3$ ms). The resulting function was then scaled in proportion to the size of the voltage step for other depolarisations (smooth curves), and superimposed on the experimentally measured currents (points). The points and the smooth curves both include a component of steady current. The lowest trace (-68 mV) shows that the fit is reasonable for a smaller subthreshold step. The peak of the capacity transient in the upper three traces (-41 , -28 , -3 mV) was off scale and is not resolved. Fibre T46-1.

Fig. 3 Voltage dependence of sodium current and sodium permeability in the rabbit Purkinje fibre. *a*, measured currents corrected for capacity and steady current and plotted against membrane potential. Inward values represent peak inward currents. Outward peaks were difficult to resolve accurately because of rapid activation at strong depolarisations. Outward values were therefore measured isochronally at 1.8 ms. *b*, P_{Na} -voltage relationship in the rabbit Purkinje fibre. Sodium permeability calculated from *a* using equation (1) and normalised. When expressed in terms of the external cylindrical surface area of the preparation, maximal P_{Na} is $6.3 \times 10^{-3} \text{ cm s}^{-1}$. This estimate incorporates some resting inactivation at the holding potential, -77 mV. Fibre T46-1.

Sodium current was separated from capacitive current by the procedure shown in Fig. 2. The time course of the capacity transient was obtained from the response to an 18-mV step which was below the threshold for I_{Na} . The smooth curves show this time course, after scaling appropriate to the amplitude of other voltage steps. As expected, the smooth curve provides a good fit to the capacity transient during an even weaker step (record labelled -68 mV). At stronger depolarisations, I_{Na} can be seen as the difference between the smooth curve and the data points. The activation of I_{Na} can be largely separated from the decay of the capacity transient during the step to -41 mV. Temporal resolution is less satisfactory with stronger depolarisations where I_{Na} turns on more quickly. Nevertheless, the difference signal clearly shows outward ionic current at -3 mV.

Peak ionic currents obtained by this analysis are plotted in Fig. 3*a*. The voltage-dependence of peak I_{Na} is qualitatively similar to that found in other excitable tissues. The reversal of the ionic current takes place near -9 mV. This value is reasonably close to -3 mV, the value calculated from the Goldman-Hodgkin-Katz potential equation^{20,21} with P_{Na}/P_K set at 12 (ref. 22) and Na and K activities estimated by ion-sensitive microelectrodes^{23,24}. The calculated value is close to zero membrane

potential because the external Na activity is close to one-twelfth of the internal K activity.

Figure 3*b* shows the voltage-dependence of the sodium permeability P_{Na} , calculated from the data in Fig. 3*a* by the following equation^{20,21}

$$P_{Na} = \frac{I_{Na}}{(Na)_o} \frac{RT}{EF^2} \frac{\exp(EF/RT) - 1}{\exp((E - E_{Na})F/RT) - 1} \quad (1)$$

where E is the membrane potential (inside minus outside), E_{Na} is the measured reversal potential, and R , T and F have their usual meanings. P_{Na} shows a sigmoid dependence with membrane potential, varying from almost no activation at -50 mV to nearly full activation at 0 mV. The smooth curve is drawn for half maximal activation at -26 mV and a maximal P_{Na} of $6.3 \times 10^{-3} \text{ cm s}^{-1}$. This estimate is close to that reported by Adrian and Marshall for rat skeletal muscle²⁵.

Fig. 4 Influence of membrane potential on I_{Na} inactivation. *a*, membrane currents elicited by depolarisations to -13 mV following 200-ms prepulses to -54, -62, -71, -80, -89 and -97 mV. Only the last 2 ms of the prepulse are shown. Peak currents following prepulses to -89 and -97 mV largely superimpose. *b*, Sodium inactivation curve obtained by plotting the amplitude of the inward current (corrected for capacity transient) against prepulse potential. The normalised data were fitted by the equation $h_{\infty} = 1/(1 + \exp(E + 72/5.45))$. Holding and test potential, -13 mV; pulsing rate, 0.2 Hz. External cylindrical surface area, 0.0024 cm^2 . Fibre T42-3, 5.4 mM Ca, 22 °C.

The phasic nature of the sodium permeability is attributed to a process termed sodium inactivation²⁶. Figure 4*a* shows one method for studying the voltage-dependence of inactivation. I_{Na} was elicited by step depolarisations to a fixed test potential (-13 mV). The test pulse was preceded by 200 ms prepulses to various voltage levels. As the current records indicate, the amplitude of I_{Na} was largest following a prepulse to -97 mV, while almost no sodium current was seen following a prepulse to -54 mV. The analysis of these data and others from the same

Fig. 5 Test of voltage control during I_{Na} . Superimposed records of recorded potential (top) and membrane current (bottom) during long and short clamp pulses. Brief pulse was terminated at peak P_{Na} . Good voltage control is indicated by the rapid decay of inward current following repolarisation. Traces are the average of two sweeps. Fibre T46-1.

experiment is shown in Fig. 4b. The amplitude of the I_{Na} transient displays a sigmoid dependence on prepulse potential. After normalisation, the data were fitted by the function

$$h_{\infty} = \frac{I_{Na}}{(I_{Na})_{\max}} = \frac{1}{1 + \exp((E - E_h)/k)} \quad (2)$$

where $E_h = -72$ mV and $k = 5.45$ mV. Table I presents data from a total of five experiments where $E_h = -74 \pm 4$ mV and $k = 5.36 \pm 0.71$ mV (mean $\pm$ s.e.m.). Equation (2) and very similar parameter values were used by Weidmann¹⁹ in his studies using maximal upstroke velocity as an index of P_{Na} . Our results resemble Thompson's data for rabbit Purkinje fibres in the double sucrose gap¹⁷, but differ from observations of Dudel and Rüdel in sheep Purkinje fibres²⁷. At 20 °C, Dudel and Rüdel found complete inactivation ($h_{\infty} = 0$) for potentials positive to -90 mV. We have seen similar behaviour in three exceptional cases in which the full inactivation curve was not determined. The data in Table I are representative of over 90% of our preparations, in which substantial I_{Na} is available at -85 mV, the normal resting potential at physiological temperature¹⁶.

The current signals in these experiments satisfy several criteria for adequate voltage control¹⁻⁸: (1) the inward current record shows a smooth decay, with no secondary humps or 'abominable notches' (Fig. 1); (2) the time course of the current remains unchanged when its magnitude is varied by prepulse inactivation (Fig. 4a); (3) the measured reversal potential lies close to the theoretically expected value (see ref. 5); and (4) activation is a gradual function of membrane potential, extending over a range of about 50 mV (Fig. 3b) as in other excitable tissues. There is no indication of the sharp voltage-dependence predicted for certain conditions where voltage control is poor^{2,6}.

Figure 5 shows an additional test for adequate clamp control which has been proposed in experimental^{14,17,28} and theoretical⁴ studies. The depolarising command pulse is terminated just as P_{Na} reaches its peak. If the membrane potential is adequately controlled, the 'tail' current should follow a smooth, rapid decay; if not, the current may be hooked or show the waveform of an inverted action potential. As Fig. 5 indicates, the experimental trace does in fact show a fast shut-off following the repolarisation.

Experimental evidence for adequate voltage control is compatible with rough calculations based on electrical properties of the preparation. Previous experiments¹⁶ provide an upper estimate of the effective external series resistance, $R_s \leq 3.3 \Omega \text{ cm}^2$. With this value, the voltage drop along R_s can be calculated for the maximum I_{Na} in Fig. 3 (120 nA) and the external surface area of the preparation (0.0032 cm^2). Thus $(120 \text{ nA})(3.3 \Omega \text{ cm}^2)/(0.0032 \text{ cm}^2) = 0.12 \text{ mV}$. This radial voltage error is negligible. Longitudinal voltage nonuniformity may be calculated by taking an experimental estimate of the longitudinal resistivity, $R_l = 450 \Omega \text{ cm}$. For the measured radius of $80 \mu\text{m}$, the axial resistance per unit length is $r_l = 2.17 \text{ M}\Omega \text{ cm}^{-1}$. The negative slope region of the I - V relationship in Fig. 3 corresponds to a membrane resistance per unit length of $r_m = -6.3 \text{ k}\Omega \text{ cm}$. From these values, one calculates a longitudinal space constant $|\lambda| = (|r_m|/r_l)^{1/2} = 540 \mu\text{m}$. This estimate of $|\lambda|$ is long relative to the distance from the end of the cable to the current source ($315 \mu\text{m}$). At worst, when the potential at the end of the cable is near maximum inward current, the calculated voltage difference from end to current source is only -1.7 mV . Thus, the longitudinal nonuniformity should introduce relatively little distortion in the measured characteristics.

The success of these experiments is not restricted by the properties of the microelectrodes. Current passing limitations were not a problem during the surge of P_{Na} because of the small preparation size and the low sodium concentration. The speed of clamp control was mainly limited by the product of axial resistance and membrane capacitance. Thus, at strong depolarisations, the capacity transient seriously overlaps I_{Na} activation. For analysis of activation kinetics over a wide voltage range, or effects of intracellular constituents, the method of Lee *et al.*²⁹ is clearly preferable. Our approach is very suitable, however, for analysis of sodium permeability over the voltage range where action potentials are initiated. It offers the possibility of studying sodium channels and their pharmacological modification in intact cardiac tissue free from enzymatic treatment. Further work will be needed to establish how cardiac sodium channels differ from those in other excitable membranes.

This work was supported by a grant from the USPHS and an Established Investigatorship of the American Heart Association. We thank Dr S. A. Siegelbaum for advice and help throughout the course of this work.

Sodium current in single heart muscle cells

A COMPLETE description of the sodium current, I_{Na} , in heart muscle has not been obtained despite the practical importance of such information as a rational basis for the therapy of arrhythmias. I_{Na} has been examined under voltage clamp using micropipette¹ or sucrose gap methods², but the adequacy of spatial control of voltage has been questioned and temporal resolution of the early kinetics has been unsatisfactory and results therefore inconclusive³. These problems reflect the fact that heart muscle is a syncytium with restricted extracellular compartments. One of the more favourable preparations is rabbit Purkinje fibres⁴ and Colatsky and Tsien⁵ have recently performed voltage clamp studies on them with the two micropipettes technique. They have demonstrated the feasibility of this approach when proper precautions are taken⁵. Quite a different approach has been taken by other investigators such as Mehdi and Sachs⁶ and Powell *et al.*⁷⁻⁹, who have dispersed individual heart muscle cells and examined them with micropipette techniques. In this way the complex geometry is greatly simplified although the enzymes used in dispersion may pose another set of problems. We have followed this second approach and have isolated individual heart muscle cells from adult rats with a modified version of the dispersion method reported by Powell and Twist⁹. To perform electrophysiological studies we have sucked single cells into a suction pipette and used a technique which allows voltage clamp and internal perfusion¹⁰. I_{Na} has been isolated by suppression of other cardiac currents and its kinetics separated from the capacitive current transient. The success of the present approach indicates its potential usefulness in cardiac electrophysiology.

The suction pipette method is similar to that used in snail neurones and the details have been published elsewhere¹⁰. The main difference in the present experiments is that the tip diameter of the suction pipette was smaller, about 20 μm , and the measured tip resistances ranged from 150 to 250 k Ω . Series resistances determined from the peak amplitude of the capacitive current transient have similar values, indicating that the

tip resistance was mainly responsible. For currents less than $\sim 2 \times 10^{-8}$ A, the effects were negligible but for larger currents series resistance compensation¹⁰ was used. The rise time of the voltage clamp step was 10 μs and the capacitive current transient had a single time constant 100–200 μs in duration. Current-time records during single clamp runs were digitised every 5 μs using a 12-bit digital oscilloscope with a 2 K memory (Nicolet 575) and stored on a digital tape recorder (Kennedy Model 9700). Currents produced by voltage steps equal in amplitude but opposite in sign could be added to remove leakage and shunt currents and the linear components of the capacitive current. The external solution for separating I_{Na} had the following composition in mM: sodium isethionate, 120; CsF, 5.4; Mg_2SO_4 , 2.85; NaH_2PO_4 , 0.42; NaHCO_3 , 25; glucose, 5.5; pH 7.5 when equilibrated with 95% O_2 , 5% CO_2 . In the early experiments 5.0 mM tetraethylammonium was added to both internal and external solutions but later its use was discontinued due to its lack of effect. Cs^+ was used to substitute for K^+ in the internal solution which had the following composition (mM): CsF, 130; NaHCO_3 , 16; glucose, 5.5, pH 7.3 when equilibrated with 95% O_2 and 5% CO_2 . Experiments were carried out at 23 °C. The general procedures for obtaining individual, isolated beating adult rat myocytes have been described⁹ and details as well as biochemical characteristics of the cells prepared in this way will be published elsewhere.

The structural characteristics of single dispersed myocytes are similar to those already reported^{11,12}. The individual cells are separated at the intercalated disks, are approximately cylindrical, but have longitudinal grooves and transverse ridges with T-tubule openings near these ridges. Cell dimensions were 15–25 μm radius and about 100 μm length. Under the dissecting microscope the cells were beating in solution before and after aspiration, but during maintained suction visible beating ceased. In low or zero Cl^- solutions resting potentials were –70 to –90 mV (ref. 7) and the cardiac action potential had the shape shown in Fig. 1a. The short duration of the plateau may be related to the rapid heart rate of the rat (4 Hz); similarly shaped action potentials for intact rat ventricle¹³ and dispersed rat myocytes⁸ have been reported. Potassium currents were suppressed by Cs^+ substitution for internal and external K^+ , Ca current was suppressed either by Co^{2+} and/or zero Ca^{2+} solutions and Cl^- current was suppressed by isethionate[–] and F^-

Fig. 1 Membrane potential and I_{Na} in single rat heart muscle cells. Individual myocytes were obtained by exposing rat ventricles to Krebs–Henseleit solutions containing 0.1% collagenase (Sigma type 1) and 0.1% hyaluronidase (Sigma type 1) according to the methods of Powell *et al.*⁷⁻⁹. *a*, Record of an action potential obtained from a single rat heart muscle cell in zero Cl^- solutions using the suction pipette method. Stimulating current was delivered by current clamp. The resting potential is –80 mV. The action potential amplitude is about 100 mV with a 20 mV overshoot and was corrected for the voltage drop across the tip resistance. The plateau phase is shortened and similar configurations in rat heart muscle have been reported^{8,13}. *b*, *c*, I_{Na} records uncorrected for capacitive, leakage and shunt currents. I_K , I_{Ca} and I_{Cl} have been suppressed by substituting Cs^+ for K^+ , Co^{2+} for Ca^{2+} and isethionate[–] and F^- for Cl^- . The traces are from the same cell in 100% (*b*) and 0% (*c*) external Na solutions. In (*b*) I_{Na} is resolved after about 150 μs and a clear reversal of currents is observed. In (*c*) only outward current appears. In both cases, the peak inward or outward current appears and then disappears within the first 2–6 ms depending on the magnitude of the step voltage change. As the step potential becomes progressively higher, peak current appears more quickly. Holding potential, $V_H = -90$ mV. $1-2 \times 10^{-9}$ A of inward current was usually required to achieve this V_H . Each voltage trace represents a 10 mV increment from V_H .

Fig. 2 I_{Na} currents after subtraction of leakage, shunt and linear capacitive currents and their I - V relationships. *a*, I_{Na} values from a single myocyte in 50% $[Na^+]_o$. *b*, Same cell in zero $[Na^+]_o$. $V_H = -90$ mV and corresponding clamp potentials are indicated besides each current trace. Activation and inactivation are apparent and are faster at higher voltages. A small outward current persists in zero $[Na^+]_o$ solutions. The reason for the slower kinetics in (*b*) is explained in the text.

substitution. After suppression of I_K , I_{Ca} and I_{Cl} , the current-time records and associated clamp potentials in 100% Na solutions are shown in Fig. 1*b*. The currents in these records have deliberately not been corrected for leakage or capacitive components and show that early I_{Na} is clearly distinguishable from the capacitive transients. In the photographic reproductions the latter appear mainly as discontinuities after the step depolarisations. As voltage amplitudes are increased above threshold the inward current becomes progressively larger and faster, but then the amplitude decreases as the voltage step approaches E_{Na} . The currents reverse as the steps go positive

with respect to E_{Na} . A small delay preceding activation is present and is more apparent in Fig. 2. I_{Na} also shows inactivation; this process is about 4–8 times slower than activation. After leakage subtraction it appears that inactivation of inward I_{Na} is complete. The tail currents occurring during repolarisation are capacitive and have a single time constant of 100–200 μ s which is similar to that measured at the onset of the step depolarisations. When Na^+ is completely replaced by Tris or isotonic sucrose solution, I_{Na} is outward only, as Fig. 1*c* demonstrates. In the absence of extracellular Na^+ , a small steady outward current persists and this current is often smaller at more

Fig. 3 Effects of changes in $[Na^+]_o$. *a*, Current-voltage relationship of peak inward and outward Na^+ currents in external solutions containing varying amounts of sodium as follows: 50% ($\bullet$), 25% ($\blacksquare$) and zero ($\blacklozenge$). Same cell as in Fig. 2. The peak currents are sensitive to both voltage and $[Na^+]$. The null potential of this current shifts to the left along the voltage axes as $[Na^+]_o$ decreases and becomes totally outward as the sodium in the external solutions is reduced to zero. *b*, Changes of E_{Na} in relation to log changes of $[Na^+]_o$. Each point is from a different myocyte. The solid line represents the Nernst potentials for $[Na^+]_i = 16$ mM, the internal perfusate concentration. Na^+ concentrations are: 100% ($\circ$), 75% (Δ), 50% ($\bullet$), 25% ($\blacksquare$), 10% ($\odot$) and 1% ($\blacklozenge$).

positive voltages leading to a crossover of the steady outward currents at long times. This may reflect the voltage-dependence of the inactivation process but could also be due to a voltage-dependent blocking action of Cs^+ upon I_{Na} similar to that observed in squid axon¹⁴. When I_{Na} was outward, it could be abolished by replacing Na with Cs. The effect appeared 1 to 2 min after solution change and was complete after 10–20 min indicating that internal perfusion can effectively control intracellular ionic composition.

As Na^+ substitutes we used Tris or tetramethylammonium (TMA) ions or isosmotic replacement of NaCl with sucrose. TMA had deleterious effects within a few minutes and the cells did not tolerate exposures to Tris for periods longer than 15 min. At shorter times, however, Tris was a reasonable substitute. The effects of Tris or sucrose substitutions on I_{Na} were similar.

The current-voltage relationship in 100% Na_0 solutions often had a steep negative resistance region indicating inadequate voltage control. This problem seldom occurred when $[\text{Na}^+]_0$ was reduced to 50% or less as shown in Fig. 3a. The relationship between peak I_{Na} and voltage in the different solutions was derived from traces of currents such as those shown in Fig. 2 which were obtained after subtraction of leakage and linear capacitative components. Lowering $[\text{Na}^+]_0$ did not appear to alter the basic Na^+ conduction mechanism. Thus, in low Na^+ solutions currents were reduced in accordance with the independence principle and kinetics and normalised conductance-voltage relationships were similar. The slower kinetics in zero Na_0^+ (Fig. 2b) compared to 1/2 Na_0^+ (Fig. 2a) reflect the effects of experimental times greater than 30 min which were required to complete the studies in several different external solutions. Similar changes may also occur at prolonged times in a single test solution. We used chord conductances for conductance calculations because the instantaneous I - V curves were linear. The G_{Na} - V curve at its steepest increased e -fold for about 10 mV of depolarisation, which is similar to the findings of Colatsky and Tsien⁵. I_{Na} could also be inactivated by depolarising prepulses and the extent of inactivation was determined by the duration and amplitude of the prepulse.

The reversal potentials, E_r 's, for leakage-corrected I_{Na} are similar to those predicted by the Nernst potentials for the internal and external concentrations of Na^+ used (Fig. 3b); this indicates a high selectivity of the conductance for sodium ion.

The degree of complexity of membrane geometry in the present preparation needs to be examined in detail because a major weakness in voltage clamp studies of heart muscle has been an inadequate consideration of such complications³. Towards this end impedance studies are now underway. Calculations of surface area derived from the capacitative current transient are slightly larger than calculations assuming a right cylinder of the dimensions referred to but some of the discrepancy might be due to the longitudinal grooves and transverse ridges present in these cells. A contribution from T-tubules is also possible, but a complicated equivalent electrical circuit may be unlikely because the capacitative current transient is a single exponential function. Spatial control of voltage seems adequate as there are no notches on the current records, the negative slope region of the I - V curves in solutions with 50% Na or less is not overly steep, that is, peak inward current increases gradually with voltage in this range and lowering $[\text{Na}^+]_0$ reduces currents without altering kinetics or voltage-dependence. With the present method it is possible to examine I_{Na} in the outward direction only and avoid negative resistances where voltage control is most difficult (Fig. 3a, zero Na_0^+ curve). In three instances, we were able to compare recorded values for the maximum rate of rise of the action potential dV/dt_{max} with computed values using I_{Na} and C_m calculated from the capacitative current transient, and these were in reasonable agreement. As all other currents were suppressed it cannot be concluded, however, that under normal circumstances dV/dt_{max} and I_{Na} would be equivalent.

The effects of enzyme treatment upon I_{Na} require some comment. The high selectivity of G_{Na} and the similarity of our

G_{Na} - V curve to the P_{Na} - V relationship obtained by Colatsky and Tsien⁵ in the absence of enzymes suggest that enzyme treatment has few effects. Moreover, collagenase treatment of mammalian skeletal muscle had little or no effect on resting or action potentials¹⁵.

In *Helix* neurones, the enzyme trypsin does not alter the electrical properties of I_{Na} but it does abolish tetrodotoxin (TTX) sensitivity¹⁶. We found that myocyte I_{Na} was blocked by TTX but unlike axons, the blockage requires micromolar concentrations and is voltage-dependent, being less complete at more positive potentials. A voltage-dependent action of TTX on dV/dt_{max} in untreated guinea pig papillary muscle cells has been reported¹⁷ as having the large concentration requirements. Therefore the presently reported TTX effects are probably not due to enzymatic actions but result either from differences in all Na channels, or a small number of TTX-resistant channels.

A full description of I_{Na} is clearly feasible as the present report and that of Colatsky and Tsien⁵ indicate. Our methods also provide the capability for simultaneous voltage clamp and internal perfusion of individual cardiac cells. This approach will be very useful for future electrophysiological studies on heart muscle and similar approaches are likely to be successful in other body tissues.

Physiological role of ATP-driven calcium pump in squid axon

It has been proposed that the regulation of the ionised calcium concentration inside many excitable and non-excitable cells is mediated by a Na-Ca countertransport mechanism where the Na electrochemical gradient provides the energy to maintain low levels of intracellular Ca^{2+} (refs 1, 2). Two recent observations, however, provide evidence consistent with the idea that Ca extrusion in squid axons is mediated, at least in part, by an ATP-driven Ca pump of the type observed in red blood cells^{3,4}. First, in the absence of a Na gradient across the membrane there is an ATP-dependent 'uphill' extrusion of Ca which persists in the absence of external Na, Ca and Mg (ref. 3). And second, in Ca-injected unpoisoned axons, 50–90% of the Ca efflux can occur as an 'uncoupled' flux—that is, Ca efflux not accompanied

Fig. 1 Effects of Na_i , Na_o and ATP on the activation of Ca efflux at physiological Ca_i^{2+} concentration (axon 010678A, 530 μm). The composition of the dialysis solution was (mM): K^+ 310; Na^+ 60; Mg^{2+} 4 in excess of the ATP concentration; Tris^+ 5; Cl^- 79; aspartate 310; EGTA 1; glycine 330; oligomycin 10 $\mu\text{g ml}^{-1}$. The osmolality was 980 mosM and the pH (17 °C) 7.1. ATP and phosphoarginine (PA) were obtained from Boehringer as sodium salts and were stored at -90 °C as stock solutions (250 mM at pH 7.1). The ATP solution contained in addition 250 mM MgCl_2 . The composition of the standard artificial seawater was (mM): Na^+ 440; K^+ 10; Mg^{2+} 50; Ca^{2+} 10; Tris^+ 10; Cl^- 580; EDTA 0.1. The osmolality was 1,000 mosM and the pH (17 °C) 7.6. Tris^+ was used as Na^+ substitute. Removal of Na_i or Na_o and Ca_o was carried out without changing the other constituents. The nominally Ca-free media contained 0.5 mM EGTA and no added Ca. The axon was preincubated for 1 h in KCN before dialysis. At zero time, the dialysis began with the indicated solution plus radioactive Ca. The fluid superfusing the axon (1 ml min^{-1}) contained nominally 1 mM KCN and was collected at 4-min intervals. An appropriate volume of a scintillation mixture was added and the samples counted in a scintillation counter. The reduction following the initial rise in Ca efflux is a consequence of the ATP washout. The arrows refer to addition of ATP + PA to the internal medium.

by the uptake of Na, Ca or Mg (ref. 5). The existence of two apparently separate mechanisms for Ca transport, Na-Ca exchange and an ATP driven Ca-pump, raises the question of whether, in normal conditions, both mechanisms participate in the maintenance of the physiological $p\text{Ca}$. To be of any use in controlling the $p\text{Ca}$ of the nerve, the mechanism responsible must be able to operate at normal Ca_i^{2+} concentrations, $<10^{-7}$ M (ref. 6). We now present evidence showing (1) that in squid axons with physiological levels of Ca_i^{2+} most of the Ca efflux can be accounted for by an ATP-dependent system with high affinity for Ca_i^{2+} and ATP and which can operate in the complete absence of external Na and Ca; and (2) that a Ca transport mechanism with a low affinity for Ca_i^{2+} and ATP and extremely sensitive to Na_i , Na_o and Ca_o can contribute substantially to the total Ca efflux only at Ca_i^{2+} well above the physiological Ca_i^{2+} concentrations.

The present experiments were carried out on giant axons of the squid *Loligo pealei*, using the internal dialysis technique to control the intracellular concentration of low molecular weight solutes. Washout of internal ATP was achieved using glass dialysis capillaries. The amount of ADP produced by hydrolysis of exogenous ATP was minimised by adding 5 mM phosphoarginine to the dialysis solutions.

The dependence of Ca efflux on Na_i , Na_o and ATP was determined at a Ca_i^{2+} concentration of 0.04 μM (physiological levels of Ca_i^{2+} are between 0.02 μM and 0.1 μM). After the washout period a steady Ca efflux of ~ 2 $\text{fmol cm}^{-2} \text{s}^{-1}$ was obtained (Fig. 1). Changes in the Na electrochemical gradient (removal of internal Na at constant external Na and vice versa) had no effect on Ca efflux. In contrast, addition of as little as 10 μM ATP, in the absence of Na_o and Ca_o , led to a significant increase in Ca efflux. In the presence of 3 mM ATP removal of Na_i had no effect on Ca efflux, whereas readdition of external Na and Ca increased Ca efflux slightly and reversibly. Note also that the ATP dependent Ca efflux can operate at very low Ca_i^{2+} , as the levels of Ca efflux at 0.02 μM Ca_i^{2+} are appreciably higher than the basal Ca efflux observed in the absence of ATP (Fig. 1).

Figure 2 shows that the ATP dependent, Na_i and Ca_o independent (uncoupled) Ca efflux constitutes most of the Ca efflux at physiological Ca_i^{2+} concentrations, with a $K_{1/2}$ for Ca_i^{2+} of ~ 0.18 μM . On the other hand, the ATP independent, Na_i

and Ca_o dependent Ca efflux is minimal at physiological Ca_i^{2+} concentrations and shows no sign of saturation up to ~ 1 μM Ca_i^{2+} . When internal ionised calcium was raised to 80–110 μM , the Na_i dependent Ca efflux rose to 680–750 $\text{fmol cm}^{-2} \text{s}^{-1}$ and was highly sensitive to internal Na concentration (data not shown). In *Dorytheutis plei* at physiological Ca_i^{2+} and Na_i concentrations, $>95\%$ of the Ca influx was independent of Na_i and Na_o and increased linearly with the external Ca concen-

Fig. 2 Effect of internal ionised Ca on the Ca efflux components in dialysed squid axons. $\text{Na}_i = 65$ mM; temperature 16.5 °C. x, Ca efflux measured in ATP-dialysed axons (3 mM ATP + 5 mM PA) bathed in standard artificial seawater. o, Ca efflux measured in ATP-dialysed axons in solutions with Na_i and Ca_o both zero ('uncoupled' component). •, Na- and Ca-dependent Ca efflux measured in ATP-free axons. ■, Ca efflux measured in ATP-free axons with Na_i and Ca_o both zero (leak component). Ionised calcium in the dialysis medium was controlled by varying the ratio (CaEGTA)/(free EGTA) at a constant total EGTA of 1 mM. The apparent dissociation constant for the CaEGTA complex was chosen as 0.15 μM^2 . The numbers above the experimental points represent the number of determinations. The physiological range of Ca_i^{2+} concentration is indicated by the horizontal arrow.

Fig. 3 Effect of internal ATP on the 'uncoupled' and Na-Ca dependent components of the Ca efflux. Ordinate: Ca efflux relative to the maximum efflux obtained with 1 mM ATP. Abscissa: ATP concentration in the dialysate in μM . The ATP in the axoplasm was buffered by adding 5 mM phosphoarginine to the dialysis medium. ●, Steady state Ca efflux level in the absence of external Na and Ca ('uncoupled'). ○, Na-Ca dependent Ca efflux. Half activation was obtained at 30 μM and 230 μM respectively. In most of the experiments shown above, the ATP dependence of both components was tested in the same axon. Once the ATP from the fibre had been removed by dialysis (washout 1–2 h) Na and Ca were removed from the external medium and increasing amounts of ATP (10, 50, 200, 1,000 μM) were sequentially added to the dialysis fluid. Once the ATP dependent 'uncoupled' Ca efflux had reached a steady state corresponding to each ATP concentration, the external Na and Ca sensitivity was tested in square pulse fashion. The number to the right of the experimental points represent the number of determinations. The curves were drawn by eye. The mean temperature was 17 °C.

trations. With 3–4 mM external Ca the influx of Ca was $\sim 38 \text{ fmol cm}^{-2} \text{ s}^{-1}$; this 'leak' influx closely matches the magnitude of the uncoupled Ca efflux observed here and obtained in comparable conditions. With high Ca^{2+} concentrations Ca influx was mainly through the Na-Ca exchange mechanism⁹.

Although ATP is not essential for the Na-Ca exchange mechanism to operate, it is known that the addition of ATP brings about an increase in the rate of that exchange¹⁰. Figure 3 shows several experiments where the relative rate of the 'uncoupled' Ca efflux and the ATP-stimulated Na-Ca exchange are plotted as a function of the ATP concentration in the dialysis solution. It is clear that the 'uncoupled' component shows a much higher affinity for ATP ($K_{1/2} = 30 \mu\text{M}$) than the Na-Ca exchange ($K_{1/2} = 230 \mu\text{M}$).

The experiments described above indicate the existence of two components of Ca efflux in squid axons: (1) uncoupled Ca efflux and (2) Na-Ca exchange. The properties of these components suggest that they indeed represent two different mechanisms for Ca translocation.

The 'uncoupled' Ca efflux, which has all the properties of a Ca pump, operates in the physiological range of Ca_i^{2+} concentration, thus playing a fundamental part in the regulation of intracellular ionized calcium. The Na-Ca exchange becomes more effective when Ca_i^{2+} is increased far beyond the physiological range. Although ATP hydrolysis is almost certainly involved in the operation of the Ca pump, the role of ATP on the Na-Ca exchange is still not clear. It is possible that the high Ca affinity (Ca + Mg)ATPase described by Robinson¹¹ in rat brain microsomes represents the biochemical counterpart of the ATP-fuelled Ca-pump considered here.

Phosphorylase kinase phosphorylates a brain protein which is influenced by repetitive synaptic activation

SYNAPTIC systems from mammalian brain can now be studied *in situ* using a brain slice preparation which displays most of the electrophysiological characteristics observed in intact preparations^{1,2}. We have been particularly interested in analysis of long-term potentiation (LTP), a marked and quasi-permanent increase in synaptic efficacy which is found in the hippocampal formation following a brief (1 s) train of repetitive stimulation^{3–6}. Previous work from this laboratory demonstrated a strong correlation between induction of such LTP and the apparent phosphorylation of a 40,000 molecular weight protein in synaptic plasma membranes (SEM)^{7,8}. Both LTP and the stimulation-dependent changes in the 40,000-MW protein were dependent on calcium and this cation has also recently been shown (ref. 9 and unpublished observations) to enhance the endogenous phosphorylation of a protein with a molecular weight of $\sim 40,000$. If potentiation and the phosphorylation of the 40,000-MW protein are related, with calcium being required for both, then it is possible that a calcium-dependent protein kinase might be an intermediary enzyme in the two processes. We have therefore investigated the effect of exogenous phosphorylase kinase (PBK; EC 2.7.1.38), a calcium-sensitive enzyme found in brain^{10,11}, on the phosphorylation of the 40,000-MW protein. Since several laboratories have demonstrated cyclic AMP-dependent phosphorylation of several SPM proteins^{12–15}, it was also of interest to test for the possibility that this nucleotide might be involved in the phosphorylation of the 40,000-MW protein. We report here that PBK produces a marked and highly specific phosphorylation of the 40,000-MW protein that we have previously shown to be affected by high frequency potentiating stimulation.

We assayed the endogenous phosphorylation (in the presence of either cyclic AMP or PBK) of a SPM fraction which was prepared from hippocampal slices maintained in conditions described previously². Figure 1 shows an autoradiograph from a typical experiment. As can be seen, PBK markedly stimulated the phosphorylation of the 40,000-MW protein and had no detectable effect on any other protein band. Cyclic AMP produced a significant stimulation of three bands with MWs of 85,000, 80,000 and 53,000, as has been reported by several investigators^{12–15}, but it had no effect on the phosphorylation of

Fig. 1 Autoradiograph showing the effects of PBK and cyclic AMP on the endogenous phosphorylation of SPM proteins. PBK produced a marked dose-dependent increase, compared to control (C), in the phosphorylation of the 40,000-MW protein. The final concentrations of PBK were 0.01 and 0.05 mg ml⁻¹. Quantification was based on densitometric scans as described previously⁸. Here, 0.01 mg ml⁻¹ PBK increased the phosphorylation of the 40,000-MW protein by 45% and 0.05 mg ml⁻¹ increased the phosphorylation by 140%. Cyclic AMP produced significant stimulation of the phosphorylation of proteins with MWs of 85,000, 80,000 and 53,000, but this nucleotide had no effect on the phosphorylation of the 40,000 protein. The concentrations of cyclic AMP used in these experiments were 1 and 5 μ M. Molecular weight estimates were based on comparisons with the mobilities of standards of known MW. The SPM fractions used were prepared⁸ from hippocampal slices which had been maintained *in vitro*² for ~1 h. After isolation SPMs were preincubated at 30 °C in 40 μ l of the assay buffer (10 mM MgCl₂, 50 mM HEPES, pH 7.4), at a protein concentration of 0.25 mg ml⁻¹, and after 5 min the reaction was initiated by the addition of 10 μ l of [γ -³²P]ATP (10 μ Ci, 20 μ M final concentration) and was terminated after 20 s by the introduction of 30 μ l of a stop solution which yielded concentrations of: 2.3% SDS (w/v), 5% β -mercaptoethanol (v/v), 62.5 mM Tris HCl, 10% glycerol, pH 6.8. Samples were heated in a boiling water bath for 3 min and then run on SDS-polyacrylamide gradient gels¹⁶. The gels were stained for protein with Coomassie blue, dried under vacuum and exposed to Kodak RP Royal X-Omat film for 3–4 d. Kinematic studies, to be described elsewhere, indicate that incorporation of label in this assay reflects the initial velocity of the phosphorylation reaction. Cyclic AMP and phosphorylase kinase (Sigma, in 5 μ l assay buffer) were introduced just before addition of ATP to lessen possible phosphodiesterase attack on the cyclic AMP or proteolytic degradation of the phosphorylase kinase. Addition of 5 μ l of assay buffer just before addition of ATP had no effect on the phosphorylation of control samples. In the endogenous assay of the effects of PBK, no calcium is added but it can be assumed that endogenous calcium remains following the use of 50 μ M calcium in our fractionation solutions. The question of whether calcium can stimulate the phosphorylation of the 40,000-MW protein is obviously important to our hypothesis that a stimulation-dependent calcium influx activates PBK which in turn phosphorylates the protein. Herschkovitz⁹ has shown, using Ca/EGTA buffers, that the phosphorylation of a 41–43,000-MW SPM protein is stimulated by but not totally dependent on calcium. Our preliminary experiments, also using Ca/EGTA buffers, indicate that the 40,000-MW protein is stimulated by but not totally dependent on calcium. It is important to note in this regard that although PBK has an almost absolute requirement for calcium in its phosphorylation of phosphorylase b¹⁰, PBK from tissue other than skeletal muscle retains a considerable proportion (25–40%) of its activity in the absence of calcium¹⁷; in the case of troponin, calcium enhances a basal level of PBL-catalysed phosphorylation of this contractile protein¹⁸.

the 40,000-MW component. It should be noted that several bands which undergo phosphorylation in our assay are apparently not significantly influenced by either phosphorylase kinase or cyclic AMP.

It is possible that the very specific effects of PBK could occur if the kinase were sterically hindered and hence did not have access to other substrates. We therefore tested for the effects of another soluble kinase, a cyclic AMP-dependent protein kinase from beef heart, and the results of adding this enzyme to our assay are shown in Fig. 2. Several protein substrates for this kinase are present in our membrane preparation but little or no stimulation of the 40,000-MW protein was obtained. Thus the specificity of PBK for the 40,000-MW material is presumably a true substrate specificity and not the result of steric factors.

It seems then that PBK selectively phosphorylates an SPM protein which is also strongly influenced by repetitive synaptic

Fig. 2 The pattern of incorporation of ³²P into specific bands of a SPM fraction, assayed in the presence and absence of either the holoenzyme or the catalytic subunit of the cyclic AMP-dependent protein kinase from beef heart (Sigma), is shown in this autoradiograph. In sample a, which contained the catalytic subunit at a concentration of 0.025 mg ml⁻¹, there was a significant stimulation compared to the control (b), of three bands with MWs 85,000, 80,000 and 53,000. Similarly the holoenzyme produced a large stimulation of these same bands and also increased the incorporation of ³²P into a band with a MW of 57,000. This latter band may be the regulatory subunit of the beef heart protein kinase which has been reported to undergo autophosphorylation. Densitometric quantification indicated that the catalytic subunit and the holoenzyme of cyclic AMP-dependent protein kinase produced increases in the phosphorylation of the 40,000-MW protein of less than 5% in this autoradiograph and similar values were obtained in five separate experiments. All enzymes were added just before addition of ATP and reaction conditions were identical to those in Fig. 1.

activation. Further evidence that these two treatments are acting on the same polypeptide was obtained in experiments in which endogenously phosphorylated SPM proteins were analysed in the two-dimensional gel system of O'Farrell¹⁹. As is apparent in Fig. 3, the 40,000-MW material migrates as one (and sometimes two) quite basic polypeptides, and this material shows increased incorporation following the addition of PBK. This very basic spot (or doublet) represents essentially all of the phosphoprotein material found in the two-dimensional gel at the 40,000-MW position. These data indicate that PBK probably phosphorylates the same protein which shows changes in endogenous phosphorylation following repetitive synaptic stimulation, as the kinase increases the phosphorylation of all the 40,000-MW material resolved in the two-dimensional gel analysis. Furthermore, in preliminary studies (nine separate experiments) we have found that repetitive synaptic stimulation reduces the subsequent PBK-induced phosphorylation of the 40,000-MW band.

Studies of protein phosphorylation in brain often concentrate on cyclic AMP-dependent phosphorylation, but our data

Fig. 3 Autoradiograph demonstrating the distribution in a two-dimensional electrophoretic system¹⁹, of ³²P-SPM proteins which were phosphorylated in the absence or presence of 0.01 mg ml⁻¹ PBK. The arrows indicate the position of the 40,000-MW material which migrates to a quite basic region in the isoelectric dimension of the gel. Note that in the fraction incubated with PBK there is a large increase, compared to control, in the amount of label incorporated into the 40,000-MW material. The tissue was phosphorylated in conditions described in Fig. 1 and 20 s after introduction of the [γ -³²P]ATP a 10 μ l stop solution was added to the incubation to yield final concentrations of 0.1% (w/v) SDS and 1% (v/v) β -mercaptoethanol. The samples were lyophilised, resuspended in sample buffer¹⁹, and subjected to a two-dimensional electrophoresis as described by O'Farrell¹⁹ with the exception that 3% ampholytes (pH 3.5–10.0, LKB) were used throughout.

suggest that this nucleotide is not involved in the change in the phosphorylation of the 40,000-MW protein that follows synaptic activation. We propose that the change produced in the phosphorylation of the 40,000-MW protein is more likely to be mediated by activation of phosphorylase kinase. This activation could result from the intraterminal accumulation of Ca²⁺ that is thought to occur during high frequency stimulation^{20–23}. Support for this hypothesis can be found in recent work which provides evidence that brain phosphorylase kinase is activated following stimulation^{24,25}, during seizures²⁶, and following application of putative neurotransmitters to cortical brain slices²⁷. Such an hypothesis obviously necessitates a function for phosphorylase kinase in brain other than its classical role in glycolysis, as the substrate for this process (phosphorylase *b*) has a MW considerably larger than the 40,000-MW protein. However, there is considerable evidence which indicates that PBK may in fact have several roles. Although controversial²⁸, England *et al.*²⁹ reported that the PBK-catalysed phosphorylation of troponin influences the Ca²⁺ sensitivity of the actomyosin ATPase. Interestingly, the troponin-T subunit, which is preferentially phosphorylated by PBK¹⁸, closely resembles the 40,000-MW SPM protein in MW and in its behaviour in isoelectric focusing gels³⁰. PBK has also been shown to modulate Ca²⁺ transport in the sarcoplasmic reticulum^{31,32} and the plasma membrane of skeletal muscle³³, but no protein substrate has yet been identified in this action although phosphorylase *b* inhibits the effect^{31,32}. Processes such as these are particularly exciting as potential modes of action for PBK in brain, especially in view of the possibility that the activation of PBK underlies the phosphoprotein changes correlated with long-term potentiation.

The relationship between the 40,000-MW protein changes produced by electrical stimulation and the extraordinarily long lasting increase in synaptic strength which follows such stimulation is uncertain. However, our demonstration that PBK selectively phosphorylates the 40,000-MW protein suggests new avenues for investigating the biochemical substrates of synaptic plasticity in brain.

Mitochondrial calcium uptake and oxygen consumption in cystic fibrosis

CYSTIC FIBROSIS (CF), an autosomal recessive exocrinopathy, is characterised by chronic obstructive lung disease and gastrointestinal malabsorption. Reports of exocrine gland secretory anomalies in CF¹ and increased calcium ion concentrations in some CF secretions²⁻⁵, and the importance of cellular Ca to stimulus-secretion coupling⁶ led us to study cellular Ca in CF. We previously reported an enlarged intracellular Ca pool in skin fibroblasts from subjects with CF and obligate heterozygotes, as measured by ⁴⁵Ca exchange into and out of whole cells⁷. We suggested that the altered Ca pool represented a change in mitochondrial Ca. The finding of such an alteration in cells from obligate heterozygotes, who cannot be detected as possessing the CF gene before the birth of a child with CF, suggests that the Ca finding is related to the basic gene defect in CF. The intracellular site of the altered Ca pool or pools could not be identified by studies with whole cells but required measurement of Ca uptake by isolated cell organelles. Here, we report data on Ca uptake studies with mitochondrial and microsomal fractions isolated from skin fibroblasts of subjects with CF and age-, sex- and passage number-matched controls in which mitochondria from CF cells accumulate more Ca than those from control cells. We also describe subsequent studies which show increased mitochondrial electron transport activity, measured as oxygen uptake by whole cells, in cells from subjects with CF and obligate heterozygotes. All experiments were carried out with cells at passage 4-10.

Cells were grown to confluence in roller bottles as previously described⁷, collected by rubber scraper, washed and pelleted by centrifugation in cold 0.85% NaCl. Homogenisation of the resulting cell pellet (approximately 5 mg protein) was carried out at 4 °C in 5 ml 0.25 M sucrose containing 1 mM EDTA and 10 mM Tris-HCl, pH 7.4. Fifteen strokes with a tight-fitting Dounce homogeniser were sufficient to yield 90% cell disruption as assayed by light microscopy. Three subcellular fractions were recovered by differential centrifugation: unbroken cells and nuclei at 600g for 10 min, mitochondria at 20,000g for 15 min, and microsomes at 105,000g for 45 min. Succinate dehydrogenase (SDH) activity determinations⁸ were carried out on samples of cell homogenates and isolated fractions. SDH activity per mg protein in the mitochondrial fraction was 30-fold that in the cell homogenate and there was no measurable SDH activity in the microsomal fraction. Cell fractionation was carried out simultaneously on CF and control cell lines, and Ca uptake measurements were promptly carried out on the isolated fractions following procedures for mitochondrial⁹ and microsomal¹⁰ fractions.

Mitochondria isolated from normal human skin fibroblasts accumulated Ca (Fig. 1) with a capacity and time course similar to mitochondria from other tissues¹¹. We believe this to be the first report of Ca uptake by mitochondria isolated from a nontransformed human cell type. CF mitochondria accumulated more Ca than control mitochondria (Fig. 1), and Ca uptake in CF mitochondria was about 78% more than in controls at 30 min (nmol Ca per mg mitochondrial protein: CF = 122.7 ± 10.7, control = 69.1 ± 6.0, *n* = 15 pairs). This difference was highly significant (*P* < 0.0005). In contrast to the marked difference in Ca uptake measured between CF and control mitochondria, the microsomal fractions from CF and control cells accumulated equal amounts of Ca (nmol per mg protein measured at 15 min: CF = 23.5 ± 3.1, control = 27.6 ± 3.7, *n* = 8 pairs). These findings indicate an altered mitochondrial capacity for Ca uptake in CF fibroblasts sufficient to account for the previously reported increase in CF whole cell Ca^{7,12}. The microsomal fraction from skin fibroblasts does not contribute to the CF Ca difference observed in these cells.

Ca uptake measured on whole cell homogenates after the method of Ash and Bygrave¹³ further supported the hypothesis of altered mitochondrial uptake in CF fibroblasts. In this experiment Ca uptake was determined in the presence and absence of ruthenium red, a potent and specific inhibitor of mitochondrial Ca uptake, which allowed a breakdown of the total Ca uptake by the cell homogenate into two portions, one attributable to mitochondrial (ruthenium red sensitive) and the other to all extra-mitochondrial Ca accumulation. The 8-min measurement taken after a plateau in Ca uptake was reached revealed a greater total Ca uptake in four CF cell-line homogenates compared with paired control values (110.10 and 93.43 nmol per mg protein, respectively), matched pair Student's *t*-test *P* < 0.01, and a greater mitochondrial Ca uptake in CF cell homogenates compared with paired control values (101.28 and 83.73 nmol per mg protein, respectively), matched pair *t*-test *P* < 0.005. The entire difference in Ca uptake between CF and control cell homogenates is accounted for by the increased Ca accumulated by CF mitochondria.

Fig. 1 The time course of Ca uptake per mg mitochondrial protein by CF (●) and control (○) mitochondria. Each point represents the mean of duplicate determinations on two CF and two control mitochondrial preparations. Isolated mitochondrial fractions (~500 µg protein) were washed twice in EDTA-free 0.25 M sucrose/Tris, pH 7.4, then suspended in solution A (Tris-HCl 33.6 µmol, KCl 24 µmol, MgCl₂ 3 µmol, and sucrose 25 µmol per 400 µl, pH 7.4). A 100-µl aliquot of mitochondrial suspension was delivered to each experimental tube (no. 2051 Falcon) containing 400 µl solution A at 20 °C with air as the gas phase. After a 10-min incubation, 100 µl of solution B (sodium succinate 6 µmol, KH₂PO₄ 1.8 µmol, and ATP 0.45 µmol per 100 µl, pH 7.4) was added, and 60 s later 100 nmol ⁴⁵CaCl₂ were added in a 100-µl volume. At each sampling time point a 100-µl aliquot was removed from the buffer and delivered to a microcentrifuge tube (500 µl) containing 100 µl of quench solution (20 mM EGTA and 10 µM ruthenium red). The quenching tubes were centrifuged at 12,000g for 4 min to pellet the microchondria, and a 100-µl sample of the supernatant was taken for ⁴⁵Ca determination.

Mitochondrial Ca uptake and release is vital to Ca homeostasis in many cell types. In such cells, Ca-dependent processes may be fundamentally under the influence of the mitochondrial Ca pool. Release of Ca by mitochondria gives a rapidly available Ca source and sequestration by mitochondria provides a major Ca sink. Cytoplasmic Ca, even in discrete areas of the cell, has been shown to be controlled by local mitochondria¹⁴.

One can hypothesise a mechanism to link the altered mitochondrial Ca in CF fibroblasts and the major signs associated with the disease. Much of the pathology of CF is caused by secretion of highly viscous mucus in the respiratory and gastrointestinal systems¹. Increased viscosity of CF mucus can

be attributed to high levels of Ca in these secretions^{15,16} and Ca in secretory cells is closely associated with secretory vesicles¹⁷. The enlarged intracellular Ca pool present in fibroblasts may also exist in exocrine cells in CF and may account for the increased levels of Ca in some CF secretions. Such an hypothesis demands further substantiation, but it is very significant that altered cell function in CF may be due to altered Ca homeostasis.

Ca uptake by mitochondria is a complex reaction driven by the proton gradient established across the inner mitochondrial membrane by the electron transport system^{18,19}, and this system may form the basis for the observed Ca alteration in CF cells. We have begun to study electron transport activity in CF fibroblasts by measuring oxygen uptake by whole cells.

CF, heterozygote and respective control fibroblasts were collected by trypsin digestion and suspended in Hank's balanced salt solution with 1 mg% bovine serum albumin and 200 mg% dextrose. Oxygen consumption by the suspended cells was measured with an oxygen electrode (model 53, Yellow Springs Instruments) at a cell concentration of approximately 1×10^7 cells per 3 ml buffer. Both CF and heterozygote fibroblasts consumed oxygen at a significantly higher rate than their respective control fibroblasts (n atoms oxygen per min per 10^8 cells: CF = 335.4 ± 28.7 , control = 170.7 ± 28.5 , $n = 5$ pairs, $P < 0.005$; heterozygote = 227.7 ± 17.7 , control = 156.3 ± 15.6 , $n = 8$ pairs, $P < 0.005$). The measured oxygen uptake was completely inhibited by cyanide, indicating that it was mitochondrial. These data suggest that the electron transport system in CF and obligate heterozygote fibroblasts is more active than that in respective controls, in the conditions of this study.

The apparent central role of Ca in several pathogenetic pathways in CF and the data reported here in which both mitochondrial Ca capacity and oxygen consumption are increased in CF suggest that this organelle is a suitable focus for CF investigations.

We acknowledge the use of the YSI oxygen monitor from the laboratory of Dr Beulah Gray and thank Dr Warren Warwick for his cooperation. This work was supported by a State of Minnesota Special Allocation for Cystic Fibrosis Research, NIH grant DE-00005 and the Cystic Fibrosis Foundation.

Intraspecific hybridisation and the release of mutator activity

It has been suggested by Grant^{1,2} that mutation and hybridisation may not be independent of one another as sources of genetic variation in natural populations. Indeed, it has been shown in both plants and animals³⁻⁶ that hybridisation can stimulate the production of new mutations and chromosome breakage events. The possible role of intraspecific hybridisation in inducing genetic change has recently been discussed in various contexts, especially in relation to the action of mutator genes in natural populations^{1,2,9-11}. We have previously suggested that mutator factors, which are known to induce both visible and lethal mutations and chromosome breakage, are commonly present in natural populations of *Drosophila melanogaster*. Within subpopulations, however, these mutators are genetically suppressed. On hybridisation between subpopulations, genetic suppression breaks down, resulting in the release of mutator activity and, hence, in an explosive increase in genetic variation.

Fig. 1 Progeny from a cross of *D. melanogaster* females with attached-X chromosomes and males from natural population lines or a control line. X* = X chromosomes scored for spontaneous sex-linked visible mutations in male progeny.

Clearly, these explosions of mutation, which have been documented in some natural populations^{12,13}, might have an important role in evolution and speciation. Here, we test this hypothesis of 'hybrid release' directly by determining whether intraspecific hybridisation increases the frequency of mutation above that found in the sampled natural population. Our study differs significantly from other assays of mutator gene effect¹⁴⁻¹⁶ in that mutation frequencies before and after hybridisation are compared directly. The results show that hybrid release of mutator activity does occur as the result of hybridisation, producing a severalfold increase in the frequency of mutation. Thus, hybrid release may be a major mechanism in the induction of genetic variation in natural populations and so may be a driving force in evolution.

Two sets of experiments were carried out, one assaying X-linked visible mutations, the other X-linked recessive lethal mutations. The rationale in both experiments is to determine the frequency of mutation events before and after hybridisation of a wild-type *D. melanogaster* strain with a laboratory strain. The wild-type strains included 'OK1' (which has been observed to undergo recombination in males¹⁷ and frequent chromosome breakage in spermatocytes¹⁸ after outcrossing to laboratory stocks, and is typical of the large number of wild mutator strains that have been collected worldwide⁹), 'GR' males (collected from a Grand Rapids, Ohio, population in June 1978), and 'NO' males (collected from a Noble, Oklahoma, population in July and August 1978). The inbred wild-type laboratory strain Canton-S served as a control. C(1)DX, yf (a marked attached-X stock) and Basc (a marked X chromosome balancer stock)

Table 1 Sex-linked visible and recessive lethal mutation frequencies before and after hybridisation of wild-type strains and a control stock

Males tested	Visible mutants*			Lethal mutants†		
	Mutants	Total	%	Mutants	Total	%
Wild base population	0	13,355	0	31	10,496	0.30
Wild hybrid males	43	16,501	0.26	95	10,288	0.92
Control (Canton-S) base population	0	8,590	0			
Control (Canton-S) hybrid males	0	8,803	0			

Visible mutants were scored using OK1 as the wild population following the breeding programme of Fig. 1; recessive lethal mutations were scored using Grand Rapids males as the wild population and the breeding programme described in the text.

* For wild population $P < 0.001$.

† $P < 0.001$.

were used to manipulate tested chromosomes in the breeding programmes¹⁹.

The experiment to assay X-linked recessive visible mutations is based on the transmission of *Drosophila* attached-X chromosomes (Fig. 1). The only surviving offspring of a cross between females with attached-X chromosomes and wild-type males are attached-X females and males which have received their X chromosome from their father. Thus, in the first generation of such a cross, the phenotypes of male offspring will provide a direct measure of mutation in the homozygous wild-type base population; any mutant male will have been the result of mutation in a sperm formed before hybridisation. These male progeny, however, are hybrids, being heterozygous for each of the autosomes. Mutation events that occur in their developing sperm can be detected by repeating the cross to attached-X females. A comparison of mutation frequency in the second cross (hybrid males) to that in the first cross (base stock males) will show the effect of hybridisation on mutation frequency. Data from these crosses are summarised in Table 1.

No visible mutations were found among 13,355 tested X chromosomes from the base population, but a mutation frequency of 0.26% was found among 16,501 X chromosomes in hybrid males of the second cross. In a smaller sample of chromosomes tested with NO males, no visible mutations were found among 1,726 tested X chromosomes in the first cross, whereas 9 visible mutations were found among 3,483 tested chromosomes in the second cross (0.26%). The absence of visible mutations is apparently typical of first crosses of wild lines. Although a test of second-cross hybrids has not been done with two other wild Oklahoma populations, no visible mutations have been detected in a total of 9,510 tested first-cross chromosomes (0/4,578 from Stratford, Oklahoma and 0/4,932 from Tishomingo, Oklahoma, populations). As a control, the wild-type laboratory strain, Canton-S, which has been observed to be free of mutator factors¹⁸, was also scored for spontaneous sex-linked visible mutations in base stock males and in hybrid males. No increase in mutation frequency was observed after hybridisation (Table 1). The results of this control experiment show that the increase in mutation frequency after hybridisation in the crosses with natural population lines is due to hybrid release of mutator factors in the natural population lines and not in the laboratory stock.

The most common mutations were allelic to the *singed* bristle mutation, although a variety of body and eye colour mutants, rough eye, and bristle size and shape mutations have been found in the hybrid cross. All these mutations bred true in subsequent generations. It is interesting that *singed* was also the most

common mutant type found by Green *et al.*^{20,21} in their studies of mutator genes. In addition, their mutants were unstable, suggesting that they might have been induced by the reversible incorporation of an episome or other factor into the chromosome^{20,21}. No revertants have yet been found in our mutants among only a small sample scored, but one case of a second (*singed*) mutation occurring in a mutant line (yellow body colour) demonstrates that mutation induction is not limited to the first hybrid generation.

As the X chromosomes in the first and second crosses are the same, any difference in mutation frequencies is due to the intraspecific hybridisation between lines. There is no doubt that these data show a marked increase in mutation frequency in hybrids. The visible mutations induced in a line, however, are only a small proportion of the total mutations, the largest class being recessive lethals. Thus, we confirmed these observations by assaying recessive lethal mutation frequencies in crosses equivalent to the first and second crosses described above.

Recessive sex-linked lethal mutations were detected by crossing 51 individual wild-caught GR males to Basc females. From each cross, individual GR/Basc females were then mated with Basc males, and their progeny scored for recessive X-linked lethals by noting the presence (no lethal) or absence (lethal) of wild-type males among the progeny. Any lethals would have occurred during the sperm development of the base population wild males, making this cross equivalent to the first cross described for visible mutations. Hybrid GR males from each of the 51 lines were scored by crossing single viable hybrid GR males (heterozygous for the Basc autosomes) to Basc females and repeating the original crosses.

A comparison of recessive lethal mutation frequencies in base population males and hybrid males is shown in Table 1. The hybrid release hypothesis would again predict that the frequency of lethal mutations in the hybrid males would be higher than that in the base population males. This is precisely what is found. A threefold increase in mutation frequency is observed on hybridisation.

The results from these experiments show that intraspecific hybridisation does increase the frequency of mutations, and provides strong evidence in favour of the hypothesis of hybrid release of mutator activity. It has been well established that mutators are present in many *Drosophila* populations⁹ and probably in other organisms^{4,5,22}. The assumption that mutators are genetically suppressed within subpopulations has been supported by these results and by studies of chromosome breakage in *Drosophila* spermatocytes¹⁸ which were analysed directly in the base population.

Indeed, the genetic suppression of mutator activity within a subpopulation is a consequence that is readily predictable from the action of natural selection^{6,10,11}. However, one would not necessarily expect the same genes to be involved in the suppression of mutation in different subpopulations. Thus, hybridisation would lead to heterozygosity of suppressor genes and to further breakdown by segregation in later generations. This hypothesis makes several predictions, such as the involvement of recessive rather than dominant suppressor loci, which are testable in principle. The increase in mutation frequency and chromosome breakage events observed after hybridisation could also be part of a larger syndrome of genetic and developmental changes that occur with the disruption of adapted gene complexes. Further work in this area should contribute to a better understanding of the role of mutator genes in generating the variability that has a major role in the response of populations to changing environments and to competition from other populations.

Gene numbers as measured by single-copy DNA saturation with mRNA are routinely overestimates

A MAJOR experimental approach to the elucidation of the role of differential gene expression in developmental processes has been to measure the number of different mRNA sequences in eukaryotic cells¹. This number has been obtained from the percentage of radioactive single-copy DNA rendered double-stranded during hybridisation with homologous mRNA. The percentage, appropriately corrected for the average size of mRNA and the chemical complexity of the unique DNA of the organisms, can be related to the total number of different genes expressed in the functional mRNAs of the cell type or tissue studied². The number and distribution of different mRNA sequences can also be determined by hybridising radioactive cDNA with excess unlabelled mRNA and comparing its kinetics of hybridisation with a suitable kinetic standard³. However, here, I discuss the use of single-copy DNA saturation with mRNA, and suggest that gene numbers obtained in this way are routinely overestimates.

Although both the above methods have disadvantages, especially because of difficulties in driving the reactions to completion, quite consistent measurements have been obtained for some organisms^{4,5}. However, gene numbers as determined by the two experimental approaches often differ appreciably. As shown in Table 1, it is striking that cDNA values obtained even in the most favourable conditions⁶ are generally less than those of single-copy DNA measurements. This may be due to the experimental shortcomings of the cDNA method as suggested by Hereford and Rosbash⁷.

However, we should consider the basic assumptions underlying interpretation of single-copy saturation data⁸. Most single-copy sequences were presumed to be of about the same length as mRNA and to be flanked by repetitive sequences. Single-copy sequences, isolated from randomly sheared nuclear DNA by

repeated fractionation at C_0t levels at which most repetitive sequences should have reassociated, were thought to be a representative probe of total unique DNA. Furthermore, it was thought that coding sequences were rendered double-stranded by complementary RNA sequences over their whole length due to the short tracer length (200-300 nucleotides) relative to mRNA length. Both assumptions, if invalid, would create a bias towards too high gene numbers.

Eukaryotic genomes contain much repetitive DNA⁸, most of which is intimately interspersed with unique DNA⁹. It has been shown that the reassociation analysis of sheared nuclear DNA does not reveal all the unique DNA because of its interspersion with sequence classes with faster kinetics¹⁰. The cryptic unique DNA content of a genome may be estimated by further experiments which allow the extrapolation of reassociation kinetics to zero tracer fragment length. In the first such experiment, gene number estimation was explicitly based on the total genomic unique DNA content. This rationale has also been used in other investigations^{11,12}. ³H-labelled single-copy DNA used for such saturation experiments will, however, be enriched for the fraction of single-copy DNA that is organised in long, continuous stretches. Thus, cryptic single-copy sequences will seldom, if ever, be present in such preparations, whereas sequences from long stretches of unique DNA will be almost exclusively non-cryptic and will be over-represented by a factor depending on the ratio of total unique DNA to the kinetically resolved unique DNA. This is because, from an individual unique sequence of length, L_u , using hydroxyapatite (HAP) assay in reassociation kinetics analysis of total randomly sheared DNA of median length L_m , only the fraction $(L_u - L_m + L_h)/L_u$ will seem to be unique, where L_h is the minimum length of double-stranded DNA able to bind to HAP. If L_h is 40 nucleotides and L_m 300 nucleotides, then unique sequences of L_u below 260 nucleotides will not be seen as unique, and sequences of $L_u = 500$ nucleotides will seem to be 50% unique. At a median length of 1,400 nucleotides about 80% of all sequences will seem to be unique. As the mean length of mRNAs is about 1,500 nucleotides and as almost all mRNAs are coded for by unique sequences^{1,11,13}, it is reasonable to assume that most mRNAs will be complementary to unique sequences which mainly behave non-cryptically during reassociation analysis of moderately long sheared DNA (300-400 nucleotides).

If the proposed assumption is valid, gene numbers in higher animals would need to be reduced by a factor of 0.6-1.0. However, gene numbers in plants would be more seriously affected. Higher plant genomes contain a large proportion of repetitive DNA, often amounting to more than 60% (ref. 14). Repetitive DNA sequences occur at short intervals throughout the majority of all unique DNA¹⁵⁻¹⁹, thus concealing a large fraction of unique DNA during reassociation analysis. Murray *et al.*¹⁹ have demonstrated that the majority of all unique DNA sequences in the pea are only about 300 nucleotides long. This must also be true of parsley, where we have shown that in the reassociation analysis of 300-nucleotide total nuclear DNA, only 40% of all unique DNA was revealed.

Goldberg *et al.*¹¹ have reported the first measurements of the sequence complexity of polyosomal RNA from cells of a higher plant (tobacco leaves). Here, although ³H-labelled single-copy saturation experiments indicated the presence of 27,000 different average-sized mRNAs, cDNA-poly(A)-mRNA hybridisation only revealed the presence of 12,000 different species. This and similar results of our own experiments on higher plants are listed in Table 1.

The strikingly different results obtained by the two methods suggest that the assumptions outlined above may be correct, particularly for plant gene number measurements. It may therefore be necessary to reduce single-copy DNA gene number estimates to take into account the degree of over-representation of mRNA coding sequences in the tracer single-copy DNA preparation. I propose that gene number estimates should be based on the fraction of unique DNA resolvable in reassociation kinetics of 400-nucleotide DNA.

Table 1 Comparison of gene number measurements in various species to show overestimation

Organism	Haploid genome size (nucleotide pairs)	% of scDNA (300 nucleotides) reacting with RNA	% of DNA (300-450 nucleotides) observably unique	% of DNA revealed unique in inter-spersion analysis	% of DNA assumed unique in complexity estimate	Gene number estimate based on assumed unique DNA	Gene number estimate based on observed unique DNA	Gene number estimate based on cDNA hybridisation kinetics
Yeast ⁷	1.3×10^7	20.0	95		95	4,000 (1,500)*	4,000	3,000

* Figures in parentheses are nucleotides.

In view of recent findings on gene structure^{20,21}, the assumption that during hybridisation, coding sequences are rendered double-stranded over their whole length, may also be incorrect. The organisation of eukaryotic genes may be based on the pattern of the ovalbumin gene²². Here, quite short coding pieces alternate with longer spacers of noncoding DNA belonging to the same kinetic DNA class, that is, unique DNA. However, this would mean that random shearing of genomic DNA and hybridisation with homologous mRNA would enlarge the fraction of single-copy DNA bound to HAP during the standard assay procedure. Hybridised coding sequences will bear additional single-copy DNA single-strand tails, thus apparently representing a larger coding sequence complexity than they really comprise.

Consider a coding element of DNA (an exon) of length L_e , sheared to a median length, L_m , and separated from other coding sequences by spacers of length L_s . Then, this stretch of DNA after saturation hybridisation to RNA and analysis by HAP chromatography, may form hybrids over a length of $L = L_e + 2(L_m - L_h)$ and statistically will seem to be hybridised over a length of

$$L = L_e + L_m - 2L_h \quad \text{if } L_m - L_h < L_s$$

and

$$L = L_e + L_s - 2L_h \quad \text{if } L_m - L_h > L_s$$

L/L_e will give an estimate of the overhybridisation. For an arbitrary case of an intron 200 nucleotides long, with fragments of mean length 250 nucleotides, a space of length 400 nucleotides, and HAP binding to a minimum length of 40 nucleotides of double-stranded nucleic acid, the overestimation of the length of the intron would be 1.86-fold.

A way of avoiding such overestimates would be to use the S_1 nuclease assay instead of the HAP assay. A procedure adapted for experiments where low background values are of crucial importance has been developed by Maxwell *et al.*²³

If both the above considerations are broadly correct, the new scDNA-based gene numbers would be less than the corresponding cDNA numbers. However, it seems that the two assumptions will not be wholly applicable. There will be at least some small unique DNA genes and also some genes with

intervening repetitive DNA spacer sequences, as suggested by the finding of repetitive sequences in animal hnRNA¹.

However, taking into account these modified assumptions, it seems possible to reconcile results of gene number measurements obtained by different methods. This is particularly so for differences in plant experiments. The results reinterpreted in this way will reduce gene number estimates for plants from some 30,000 to 10-15,000 different active genes in cells and tissues examined.

matters arising

Holocene reef growth on the edge of the Florida Shelf

LIGHTY *ET AL.*¹ have raised several important lines of speculation concerning the growth of reefs in the Florida and Bahamas areas and elsewhere in the Caribbean. The principal contribution of these authors has been to show an effective growth of a shallow-water coral-frame assemblage dominated by *Acropora palmata* in a period between $9,440 \pm 85$ and $7,145 \pm 80$ yr BP. This extends the evidence previously presented by Macintyre and Glynn², Adey³ and Easton and Olson⁴ for progressive growth over the past 6,000 yr.

The structures described lie within a depth range (15–30 m) which, only 40 km to the south, is accessible to Recent coral growth. One might speculate that, where conditions of growth are more favourable, reefs of the same age as those described by Lighty *et al.*¹ have been buried beneath growth covering the period from ~7,000 yr BP to the present.

Observations by Goreau and Goreau⁵ and Goreau and Land⁶ in Jamaica and by Newall and Rigby⁷ and Shinn⁸ and myself in the Florida–Bahamas province show a remarkable similarity of offshore profiles. The first element is a gentle slope to ~10–15 m depth (visible as a distinctive terrace on Fig. 1 of Lighty *et al.*¹). It is from this that the major reefs in Florida (for example, Caryfort, Dry Rocks, Alligator Reef, and so on) rise and, at least on Andros and Eleuthera, so do the major reef patches. Seawards, the surface slopes more steeply to about 30 m before plunging almost vertically in ‘the wall’ described by Ginsburg and James⁹, Goreau and Land⁶ and others. The illustrations of Goreau and Goreau⁵ seem to apply throughout the Caribbean area and suggest only two shelf-edge growth sites. Figure 1 of Lighty *et al.*¹ suggests a third, from 15 m.

We need to exercise some care in interpreting terrace levels as much of the mobile sand is derived from the excess production of the shallow-water zone (see Neumann and Land¹⁰ and Moore *et al.*¹¹). However, the widespread occurrence within these offshore platforms of exposed Pleistocene limestones indicates that we are not dealing with accretion levels but with surfaces prepared by erosion during glacial periods (compare Purdy¹²).

Now, although there are no readily

available figures for growth rates at 30 m depth there is certainly subjective evidence that they are slow. There are commonly <2 m of ‘frame’ projecting above the sand surface. In effect, relief from present-day surfaces in these depths is no greater, and may perhaps be less, than on the ‘inactive’ structures to the north.

Thus, it seems reasonable to assume first that surfaces which could have supported active coral growth at a time of rising sea level did not and, second, that the structures which we now see at 30 m are in effect the surfaces of frames which were first formed 7,000–10,000 yr ago. There is an obvious incentive to test them, using the methods described by Macintyre¹³, bearing in mind the suggestion of Macintyre¹⁴ that structures on terraces at 30–80 m depth in the eastern Caribbean do indeed represent an older phase of accretion.

We may now rephrase the question posed by Lighty *et al.*¹ What event, taking place ~7,000 yr ago, inhibited all shallow-water reef growth in the Caribbean? This growth was never able to resume in their northern area, presumably for the reasons which they accept pertaining to cold surface waters. In southern areas, however, growth began on new sites along the edge of the inner break in slope, forming the present shelf edge patches.

Lighty *et al.*¹ provide figures to show that an *Acropora palmata* reef is capable of keeping pace with rising sea level. There seems little reason to doubt this capability, but did it in fact do so? I believe that it did not and that, far from creeping upwards along the surface of a submerging slope, the principal locus of growth was established on a new and much shallower site. We are left with the conclusion that although sea level rose throughout the Caribbean there was a relatively abrupt change at ~7,000 yr BP. The broad outlines of reef morphology may have been defined at some earlier date but it was this event which determined the areas in which corals would grow. Sadly, in the area described by Lighty *et al.*¹ growth was no longer possible.

Field-work in Florida and the Bahamas was supported by the Carnegie Trust for the Universities of Scotland whose help is gratefully acknowledged.

LIGHTY *ET AL.* REPLY—The points raised by Braithwaite have been discussed in several studies of Caribbean Holocene reefs. As mentioned in our letter¹, for example, core data from a relict reef (depth 18 m) off southeastern St Croix indicated that a flourishing, shallow-water *Acropora palmata* (Lamarck) barrier reef was killed about 8,000 to 9,000 yr BP, when the shelf was flooded². Increased water turbidity related to the erosion of soil cover was thought to be responsible for the demise of this early Holocene reef. By the time water conditions returned to normal, the depth of water was too great for an *A. palmata* reef to be re-established. Subsequently, the substrate was colonised by a slowly accreting, deeper water community consisting of coral heads and octocorals.

That study² and others^{3,4} have proposed that turbidity, related to shelf erosion accompanying rising sea level, has generally prevented the continuous accumulation of Holocene reefs on wide shelf platforms of the Caribbean that are deeper than 10 m below present sea level. Although impressive reef structures are present on platforms <10 m below present sea level, these structures cannot be older than 4,000–7,000 yr BP, which is the period of initial flooding of these platforms. In south Florida, for example, the present reef tract has developed over the past 7,000 yr (ref. 5) on shallow areas of the shelf, behind the relict, shelf-edge reef of early Holocene age⁶.

Some deeper shelf areas isolated from the effects of shelf erosion might have continuous Holocene reef sections dating back to 10,000 yr BP, but no such section has yet been found.

Note, however, that in protected areas,

the fragile and rapidly growing *Acropora cervicornis* (Lamarck) is capable of constructing extensive reef structures in depths of 10–15 m (ref. 7). A Holocene reef section 33.5 m thick that consists primarily of this coral has been drilled off the lee side of the Alacran reef complex^{7,8}.

Evidence thus far indicates that Holocene reef history in the Western Atlantic is governed by factors related to shelf depth, extent of Pleistocene sediment cover on these shelves before flooding, degree of protection allowing the accumulation of *Acropora cervicornis* in intermediate water depths, and water temperatures in areas near the northerly limits of present-day reef development.

There is no evidence to indicate that a major 'event' 7,000 yr ago inhibited reef growth in the Western Atlantic. The death of shelf-edge reefs in this region is related to the time of shelf flooding, which varies from area to area, depending on local bathymetry. Some reefs (such as Galeata Reef⁹ and South Florida reef¹⁰) were, in fact, established on shallow-shelf areas around 7,000 yr BP. Another point to clarify is that relict reefs died when the rate of rising sea level was decreasing, rather than increasing, so that their death cannot be related to their inability to keep pace with the rising seas.

Braithwaite implies that reef growth, if uninterrupted, would accumulate by "creeping upwards along the surface of a submerging slope". Evidence suggests, however, that the relict, early Holocene reefs, in response to relatively rapid changes in sea level, favoured vertical over lateral growth. Reef accretion is therefore limited to linear trends that form narrow ridges; these ridges are a dominant feature of the sea floor topography of outer shelves and upper slopes in the eastern Caribbean¹⁰.

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 300 words and the briefest of replies, to the effect that a point is taken, should be considered.

Climatic signals in tree-ring chronologies for British oaks

HUGHES *et al.*¹ claim that analyses of the ring-widths of British oaks should make it 'possible to produce maps of annual or even seasonal climatic anomalies' and that these 'would provide a significantly more detailed picture of climate in the past 250 years than is now available'. This claim is based on what they regard as clear climatic signals from regression analysis applied to monthly means of temperature and precipitation and to mean ring-widths of 10–35 oaks for periods of 44–60 yr on three sites around the Irish Sea.

In fact, as their Fig. 1 shows, few of the responses to the various monthly means have 95% confidence limits that are significantly different from zero, and they are also inconsistent from one site to another. Thus the effect of temperature is positive in April and negative in May at Rostrevor but the reverse at Raehills. They do not mention any test for reproducibility on a site either by using different sets of trees or successive periods of time.

Our criticism of the work does not relate to the statistical method with its use of principal components² that Hughes *et al.* use: this has proved successful where the growth of trees is primarily controlled by one climatic factor. We believe the weakness of the claim comes from two limitations.

The first is the unsuitability of the data used. Chronologies of mean ring-widths were developed for dating by dendrochronology and are not necessarily appropriate to dendroclimatology. Monthly meteorological means are merely convenient summaries of climate: their use with oak is suspect because in different years the date of bud-burst varies by several weeks and therefore frost damage to young leaves can apply in a different calendar month. Other climatic anomalies and extremes are also obscured by the use of monthly means.

When regression analysis is used in an exploratory role, the result will be reliable

only if the major factors which affect the tree growth are included. The second limitation concerns the failure to determine the extent to which the oaks suffered damage from defoliating caterpillars, and to include this factor, if appreciable, in the analysis. Measurements of the considerable reduction of the annual growth of oak as a result of damage by caterpillars and other insects have been made in Russia³, Germany⁴, Denmark, (K. Christensen, unpublished data), and by ourselves at Oxford⁵, and warnings of the implications of this factor on dendroclimatology expressed. In the light of these considerations, the exploratory work reported by Hughes *et al.* requires evidence for reproducibility before their claim to have found clear climatic responses can be accepted. Our studies on oaks show that monthly correlations for the past 45 yr of growth with monthly climatic data are not maintained when the past 90 yr are examined.

One successful application in Europe of the Fritts method has been the outcome of preliminary studies to select a suitable parameter for use in the analysis in conjunction with a climatic stress that is strong, reproducible and not vitiated by the limitations of monthly meteorological data. Schweingruber, Bräker and Schär⁶ found that damage by insects, such as the larch-bud moth on conifers in the Alps, could be avoided by using the maximum annual density (derived by X-ray radiography) in place of ring-widths. In this way, the growth of alpine conifers on many sites in the Alps were found to be consistently related to the summer temperatures in July, August and September. We believe that the future of dendroclimatology in the British Isles needs a similar experimental approach to achieve success.

We thank members of the Department of Forestry, Oxford, for discussions.

HUGHES ET AL. REPLY—Varley *et al.*'s¹ comments are based largely on misunderstandings of dendroclimatological techniques²⁻⁷. We agree that it is not appropriate to use mean ring-width chronologies. We did not do so but rather used standardised indices of ring-width² for well-documented reasons^{5,7,8}. We did not use regression analysis of ring-widths on monthly meteorological figures as suggested¹. We stated clearly² that ring-width indices were regressed on the eigenvectors of climatic data. Consequently our results should not be compared with those referred to by Varley *et al.*^{1,9} where no account has been taken of the non-orthogonality of the data. We have maximised tree-ring variance attributable to the eigenvectors of climate, not the number of significant response function elements. The two are not simply related⁵. We discussed differences between the reported response functions. Such 'inconsistency' was ecologically expected and dendroclimatologically welcome^{5,10}. The choice of meteorological variables related to climatic reconstruction, not tree physiology⁵.

In their reference to defoliators Varley *et al.* miss the fundamental point of dendroclimatology. The material selected for site chronologies conforms strongly to a common pattern of ring-width variation². This could only be produced by factors acting similarly and synchronously on all the trees selected. No sound evidence for caterpillars doing this on British oaks is produced¹. The European examples^{11,12} concern aggregate effects on stand samples, not dendrochronologically selected material. The English example^{9,13} rests on a regression analysis of % mean latewood increment and % mean caterpillar numbers (5 trees, 20 yr) where no test of difference of the gradient from zero is given. As Varley¹³ uses the intercept to estimate effect of caterpillars it is surprising that no confidence limits are given. Incomplete statistics are given for an ecologically incomplete analysis¹⁴.

Our results are inevitably reproducible within sites as only strongly cross-dated trees are used. Chronologies from subsets of 13 and 10 trees (S. J. Milsom, unpublished data) at Maentwrog are extremely similar ($t = 15.4$, 261 yr overlap)¹⁵ as is the Rostrevor chronology¹⁶ and one from 11 nearby trees ($t = 17.4$, 223 yr overlap). Consequently they produce very similar response functions except for two differences in precipitation elements between the Rostrevor sites.

We will not use response functions to reconstruct climate. For this, we will use transfer functions between time-series of spatial anomalies of tree-rings and climatic variables³⁻⁵. Recent work (B.G., unpublished data) has shown there to be spatially coherent, temporally consistent patterns of ring-width variability. Very similar patterns for the first five eigenvectors accounted for 65% (1825-94) and

70% (1895-1964) of variance in a 15-chronology tree-ring grid between 50°-60° N and 10° W-10° E. Patterns of UK mean monthly temperature (B. Gray, unpublished data) and annual rainfall (R. Tabony, unpublished data) share similar properties. It is such coherent, consistent large-scale patterns of tree-ring variation that will be calibrated for use in reconstructing past climate. These new results further support our expectation that tree-ring chronologies from the British Isles will provide valuable proxy climatic records² and bring the generation of testable reconstructions closer.

We thank S. J. Milsom and R. Tabony for unpublished results.

Cell density is determined by a diffusion-limited process

FROM the culture of 3T3 cells in media with various viscosities, Whittenberger and Glaser¹ have concluded that the saturation density of these cells is not dependent on a diffusion-limited factor. A flaw exists in the design of their experiments. In their culture conditions the cell

Table 1 Effect of viscosity on cell density

Treatment	Cell density ($\times 10^{-4}$ cm ⁻²)
1% Serum	9.5 $\pm$ 1.7
1% Serum plus 1% Methocel	3.8 $\pm$ 0.6
1% Serum plus 1.5% Methocel	2.5 $\pm$ 0.7
1% Serum plus 2% Methocel	1.3 $\pm$ 1.1

Swiss 3T3 (clone 4A) cells were plated on 14-mm glass coverslips in Dulbecco modified Eagle's medium containing 10% serum. After 1 d single coverslips, with cells at an initial density of 3×10^3 cells cm⁻², were transferred, one coverslip each, to 15-cm plastic culture dishes. To each dish 50 ml of medium was added with or without methylcellulose (Methocel A4M, Dow) as indicated above. Treatments were in triplicate. After a further 5 d incubation in a CO₂ incubator, the coverslips were removed, washed gently with Tris-saline buffer, and the cells were fixed in formal-saline. The cells were stained and 10 fields per coverslip were counted under a microscope with an eyepiece grid (Means and s.d. are given for the 30 fields counted per treatment). Observations under the microscope indicated that there was no loss of cells during the washing and fixing procedures. The cell densities at 5 d approach equilibrium densities². Approximately the same variation of cell density with viscosity was observed when the coverslips were placed individually in 100-ml glass beakers containing 50 ml of medium with the same Methocel concentrations listed above, indicating that the geometry of the culture vessel is not critical. The low cell density observed in medium with 2% Methocel was also found when the cells, on a coverslip, were beneath a 3-mm layer of viscous medium (2% Methocel) in the bottom of a beaker, and 50 ml of medium without Methocel was placed above the viscous layer. Therefore, it is not the absence of convection currents in the bulk of the medium that leads to the lower cell density. The Methocel used was shown to be non-toxic by culturing the cells in a small volume of medium (0.2 ml cm⁻² of cells) with 1% serum, with and without Methocel, in normal culture conditions. As was observed by Whittenberger and Glaser¹, Methocel had little effect on the cell density attained. As Dextran and Ficoll give lower than normal cell densities at 5 d in normal culture conditions (attributed by the authors to 'toxicity' of these agents), these materials were not investigated.

density of 3T3 cells is limited primarily by the total supply of serum growth factors in the medium, not simply by the concentration of serum. As high viscosity does not alter the total supply of medium constituents, it is not to be expected that the cell density attained should be affected by viscosity in their conditions.

In the culture conditions that were used, with the usual small volume of medium (0.2 ml cm⁻² of cells), quiescent 3T3 cells destroy serum growth factors quickly after each medium change and before the cells have been exposed long enough for many cells to initiate DNA synthesis. Any increase in cell number after a medium change is balanced by cell loss when the concentrations of serum growth factors reach their minimum levels before the next medium change. High viscosity, if it has any effect, will prolong the period of destruction of serum factors in these conditions, and this prolongation will lengthen the exposure of the cells to a serum concentration high enough to initiate DNA synthesis. This might even increase the cell density. Therefore, the experiments of Whittenberger and Glaser

are inconclusive. Fortunately, there is a simple approach that avoids these problems.

This approach involves culturing 3T3 cells with a sufficiently large volume of medium (20 ml cm⁻² of cells) to maintain effectively a steady-state concentration of serum. Culturing 3T3 cells on a small coverslip in a large volume of medium² results in much higher cell densities and demonstrates the importance of the total supply of serum factors. For example, with a large volume of medium containing 1% serum, 3T3 cells grow to a 'saturation density' expected in 10% serum, that is, to approximately 10 times the cell density attained in normal culture conditions with a small volume of medium². Therefore, if the supply of medium is adequate, a 1% serum concentration will support the growth of high density 3T3 cells. A conclusion from the 1971 experiments, still not generally appreciated, is that the saturation density of 3T3 cells observed in normal culture conditions in 10% serum is not the cell density that is in equilibrium with 10% serum; the cell density in equilibrium with 10% serum is much higher². Instead, the saturation density observed with 10% serum is the cell density that is in equilibrium with the depleted level of serum growth factors present in conditioned medium. This is the cell density that is re-established in a 'wound'. The earlier experiments make clear that, with 3T3 cells, equilibrium conditions require a large volume of medium relative to the cell area.

As high viscosity can lower the effective local concentrations of diffusible factors in the medium but not their total supply, a meaningful test of the effect of high viscosity on cell density must be carried out in conditions that provide a large excess of medium. We have carried out such an experiment and the results are summarised in Table 1. The cell density is clearly affected by the viscosity of the medium. In the absence of methylcellulose, a high cell density is attained. As the viscosity is increased, the cell density decreases. These results demonstrate that the saturation density of 3T3 cells is in fact determined by a diffusion-limited process when the culture conditions are appropriate to test the importance of diffusion.

This work was supported in part by grants from the American Cancer Society BC-30, and by grant number CA11176 awarded by the NCI, DHEW. R.W.H. is an American Cancer Society Professor of Molecular Biology.

WHITTENBERGER AND GLASER
REPLY—Holley and Baldwin disagree with our conclusion¹ that the growth of 3T3 cells in 10% serum is not limited by the rate of diffusion of mitogens to the cell surface. They have carried out experiments similar to ours in 1% serum in a large volume of medium and they observe an effect of Methocel on the cell directly after 5 d of growth. Thus in their conditions they conclude that growth is limited by diffusion and then extrapolate from this to our previous experiments.

While the lack of an effect of a viscous polymer on growth indicates that viscosity has no effect on growth in the specified conditions, the observation of such an effect is not unequivocal, as it is possible to consider that at low serum concentrations the polymer (in this case Methocel) actually binds mitogenic factors. Also we do not know whether the results of Holley and Baldwin represent a change in the rate of growth or in the limiting cell density. In addition, we need to consider the possibility that as the concentration of serum components is decreased a new situation arises in which the rate or extent of growth does become diffusion limited.

In 1971 Holley and Kiernan² reported that incubation of confluent 3T3 cells with growth medium containing 10% serum depleted the medium of mitogenic factors, although the data were not presented. We believe that Table 1 represents a confirmation of their original data. This experiment shows that incubation of medium with confluent cells for 24 or 72 h reduced their mitogenic effect on 'sparse' growth-arrested cells by about 40%, which, because of the shape of the saturation curve, is equivalent to that of 1.5% serum. Thus serum must contain a rapidly utilised mitogen(s) and more stable mitogens. However, these experiments suggest that daily addition of fresh medium to confluent 3T3 cells should result in continued growth (at 60% of maximum) unless at high density other factors become limiting. This is essentially the conclusion of the Dulbecco wounding experiments³. The two factors that have been proposed are an effect of cell contact or a limitation by diffusion. Our experiments seem to rule out diffusion and therefore support the notion that cell to cell contact is important in this phenomenon. This is not meant to imply that in different conditions the rate of growth may not be influenced by the rate of mitogen diffusion to cells. Previous experiments by Thrash and Cunningham also seem to rule out mitogen depletion as the primary reason that cells cease to grow at high density⁵.

The implication by Holley and Baldwin that when diffusion is limited the cells are exposed to mitogen for longer periods of time is correct, but as the steady state concentration of mitogen that they see is lower, it seems unlikely that this will result in an increased cell density. While there is

Table 1 Ability of confluent 3T3 cells to deplete medium of mitogenic factors

Medium	DNA Synthesis	
	Rate per 4 h (relative amount)	% Labelled nuclei (0-24 h)
0.2%	1	0.7
2%	19	69
5%	24	71
10%	24	72
Depleted media		
24 h	14	48
72 h	16	44

Swiss 3T3 cells were plated in 2 cm² Linbro multi-well trays at 1.5×10^3 cells ml⁻¹, 1.0 ml per well, in Dulbecco modified Eagle's medium (DMEM) containing 10% calf serum. Cells to be pulsed always received L-³⁵S-methionine to 1 μ Ci ml⁻¹ to label cellular protein. After 72 h plating the medium was changed to DMEM containing 0.2% serum in 0.6 ml per well in order to render the cells quiescent. One day later the medium was changed to DMEM containing 0.2% dialysed calf serum. Three days later the medium was changed again to DMEM containing either 0.2%, 2.0%, 5.0%, or 10% dialysed calf serum (0.6 ml per well). For chronic labelling ³H-thymidine was also added to 1 μ Ci ml⁻¹, 6.7 Ci mmol⁻¹. Some dishes received medium from confluent cultures (in 35-mm dishes, 2.0 ml per 8 cm²) of 3T3 cells. This medium had been added to the cells either 24 or 72 h previously as DMEM per 10% dialysed calf serum. At the time of removal of the medium from the monolayers the cells had DNA synthesis rates of 0.6% (72-h₃ medium) or 12.8% (24-h medium) as determined by a 2-h pulse with ³H-thymidine and compared with the rate of sparse cultures. Twenty hours after the last medium change some wells were pulsed with ³H-thymidine (3 μ Ci ml⁻¹, 6.7 Ci mmol⁻¹) for 4 h and processed as described.

some loss of cells at high density this cannot be greater than the total rate of cell division of confluent cells which is generally less than 5% that of sparse cells.

Thus while we believe that Methocel affects the growth of sparse cells in 1% serum in the conditions described by Holley and Baldwin, we do not believe that this observation affects our original conclusion. If growth were limited by diffusion of mitogens in our conditions, we would have observed an effect both on the rate of growth and on the final cell density, which we did not observe.

NICHOLAS COPERNICUS

VOLUME II ON
THE REVOLUTIONS

AN ENGLISH
TRANSLATION
BY

EDWARD ROSEN

It is nearly 500 years since Nicholas Copernicus, the father of modern physics, dedicated to His Holiness Pope Paul III, his theories on physics in *De Revolutionibus Orbium Coelestium*.

Now for the modern academic, unversed in mediaeval Latin, Professor Rosen has produced a new translation, together with a detailed commentary on the complete Latin text.

This is the 2nd volume in a planned 3-volume set of the complete works of Copernicus organised by the Polish Academy of Sciences. Printed and bound to a very high standard, it is a work of great scholarship and art in its own right, and a fitting companion to Volume I, the full-colour facsimile edition published in 1972.

A History of Microtechnique

Brian Bracegirdle

This handsomely illustrated book is invaluable for an understanding of the process of microscopy. It provides a comprehensive reference for the historian of science and medicine, as well as the collector. More than 40,000 old microscope slides have been inspected and there are over 1,000 references. With the use of extensive text illustrations and photographs, this book sets down the main facts of the evolution and the development of histological methods.

Szilard and his bomb

Edward Bullard

Leo Szilard: His Version of the Facts. Selected Letters and Correspondence. Edited by S. R. Weart and Gertrud Weiss. Szilard. Pp.244. (MIT Press: Cambridge, Massachusetts, and London, 1978.) \$17.50; £12.25.

SZILARD'S scientific and technical papers were published in 1972 as Vol. 1 of his *Collected Works*. The present volume deals with political and organisational questions concerning the development of nuclear weapons before and during World War II.

Unfortunately Szilard did not write an autobiography; he did, however, record his thoughts on tape and preserved copies of letters and memoranda. The book is compiled from this material. It consists of seven chapters arranged chronologically; each has a few pages of introductory narrative skilfully patched together from Szilard's tapes and notes; and these are followed by related letters and memoranda.

The first chapter gives an account of Szilard's life from his birth in Budapest in 1898 to the end of 1938. It includes a plan by the 32 year old Szilard for a very elitist organisation intended to train a group of intelligent young men who were to form and guide public and official opinion. With hindsight one can easily see such a body turning into the Hitler Jugend or the Young Communist League. It is a little surprising that anyone as far sighted as Szilard should have taken the scheme seriously. How far sighted he was is clear from his remark, made at the age of 16, that he did not know how World War I would end but he knew that it ought to end by the defeat of Germany and Russia. By the end of chapter 1 he has passed through Berlin, London and Oxford, has taken out patents on a nuclear reactor and bomb and moved to New York.

Szilard's patents of 1934 presupposed the existence of a reaction in which the impact of a neutron on a nucleus released more than one neutron from the target. No such reaction was known, but in 1939 Hahn discovered neutron-induced fission. Szilard at once saw that neutrons would be emitted from the fragments and that there was a good chance of his reactor and his bomb becoming a reality.

The rest of the book has three themes; first, his efforts to show that a reactor and a bomb are possible; second, his attempts to restrict the spread of the knowledge of the possibility; and third, his efforts to persuade the government that nuclear bombs should not be used on Japanese cities.

The first part of the programme was entirely successful. In August 1939 Szilard persuaded Einstein to write to President Roosevelt saying that it seemed likely that a nuclear bomb could be made. This was the start of interest by the US Government in the matter. The illustration shows a reenactment of the meeting between Szilard and Einstein (no photograph was taken at the time.) A little later Szilard and Fermi invented the graphite-moderated uranium reactor which was in operation in Chicago at the end of 1942. Similar reactors at Hanford produced the plutonium used in the bomb dropped on Nagasaki. The second part was clearly hopeless; after the discovery of fission the possibility of a chain reaction was bound to occur, and did occur, to many people. The use of the bomb was also inevitable, though it is greatly to the credit of Szilard and those who supported him that they did

attempt to prevent it. Use of the bombs was inevitable in the face of the gloomy prognostications of the casualties likely to occur in the landings in Japan, which were to take place early in November 1945.

Szilard was one of the group of Hungarian emigrés who made such a deep impression on American science, particularly on theoretical physics in the 1930s and 1940s. On the whole they got on well together (Szilard tells Einstein that Edward Teller is 'besonders nett' and has letters from Wigner signed 'Wigwam'). Relationships with the management of the Chicago laboratory and of the Manhattan project were something quite different. Szilard seems to have had little confidence in any of those concerned. In fact, arguments about Szilard's patents became so acrimonious that in October, 1942, two months before his reactor first went critical, Arthur Compton, the Director of the Chicago laboratory, ordered Szilard to leave (he later relented). Relations would have been even worse had Szilard known that General Groves had drafted an order for his internment; this information has only very recently been unearthed (see Bernstein, B. G., *Inquiry*, 8 January, 1979, p27).

Why did things go so badly for Szilard?

lard? Was it just that he felt he had a mission to save the world? Was it that he and his friends were almost all foreigners? Was it perhaps that the Chicago lab had no charismatic leader, such as Oppenheimer was at Los Alamos. Oppenheimer seems to have been able to cope with General Groves and his entourage even when doing things much more open to misconstruction than anything Szilard ever did.

The book is 'Szilard's version of the facts' and of events that have had an overwhelming influence on the relationships of science and government

and on the position of science in the modern world. It is not the whole picture, there are all kinds of cross links and loose ends that need to be traced out. It is, however, a book that must be read by anyone interested in World War II or in the roots of our present scientific establishment. It is also a story about the impact of America on a very clever and deeply humane man, coming in a time of crisis from a quite different tradition. □

Sir Edward Bullard is an Emeritus Professor at the Scripps Institution of Oceanography, La Jolla, California.

Infeld's sketches

J. Rotblat

Why I Left Canada: Reflections on Science and Politics. By Leopold Infeld. Pp. 212. (McGill-Queen's University Press: Montreal and London, 1978.) \$16.95.

LEOPOLD INFELD was internationally renowned for his important contributions to theoretical physics, as well as for his gift to write on science for the layman. But he was also an extraordinary personality and had an unusually interesting life. He was a legend in his native Poland even in the pre-War years. I happened to do my stint of teaching in the grammar school in Warsaw where Infeld had been teaching twelve years earlier, and his exploits, mainly of a romantic nature, were still a major topic of conversation in the common room. It was many years later that I met him and got to know him.

Infeld described the first 42 years of his life in a remarkable autobiography *The Quest*, published in 1941; the book concluded with his decision to settle in Canada. But nine years later he returned to Poland for good, and there, in 1964, he continued his autobiography in a book entitled *Sketches from the Past*, which consisted of a number of essays. It is these essays, together with one written just before his death in January, 1968, that constitute the book *Why I left Canada*, published in Canada.

The long interval between the writing and publication in English has not detracted from its value. Although I had read *The Sketches from the Past* soon after their publication in Poland, I was still fascinated on re-reading them in English. The perfect translation (by Infeld's widow) has succeeded

in retaining the characteristic flavour, and the introduction and notes added to the English edition have enhanced the book, although in my opinion it would be more appreciated if it were read together with *The Quest*.

The title of the book *Why I left Canada* is taken from the title of one of the essays. In it Infeld describes the 'atom spy' hysteria in Canada in the post-War years, and which resulted in

those who obstructed his academic career in pre-War Poland for anti-semitic reasons. But above all his decision must have been influenced by the terrible devastation of Polish science brought about by the War.

The events after his return are described in the essay "Poland". Infeld did not suffer from modesty, but the essay only hints at the great heights he reached when he came back to Poland. To the public he was a hero, and officialdom treated him with reverence. As far as science was concerned his word was command, and he used his prestige and influence to foster the reconstruction of science in Poland. Naturally, his own subject did best, and in a very short time he set up the Institute of Theoretical Physics, with fifty scientists working in it.

Not all was sugar and spice. Although he was in sympathy with the regime, he was too much of an independent character to accept its rigidity. In particular, he was galled by the idolatry of Stalin, which was normal practice in Polish science in the early 1950s. At one time he even re-

Einstein and Infeld

the hounding of Infeld and his family after he had made a short visit to Poland in 1949. He was planning to spend the following year in Poland on a sabbatical, but when his Canadian passport was withdrawn he decided to remain in Poland for the rest of his life. The Canadian Government re-ven-ge-d itself in the subsequent cancellation of Canadian citizenship of his two children, who were born in Canada.

Although the harassment in Canada was the direct reason for Infeld's return to Poland, it is very likely that he would have done it in any case. There were several reasons for this. Politically, he had always been on the left (he considered himself a Marxist); the new regime in Poland therefore appealed to him much more than the 'flesh pots' of Canadian life. There may also have been an element of personal satisfaction in getting the upper hand over

gretted having returned to Poland. But a few years after Stalin's death the atmosphere became more relaxed, and later he was even able to write about it in the book published in communist Poland.

The essay "Einstein" describes the contacts with him in the last years of Einstein's life. Infeld had a very successful collaboration with Einstein in the 1930s, and he resumed it after the War, first directly, when Infeld was still in Canada, and later by correspondence. Although Infeld did not agree with Einstein about the unified field theory, they worked in harmony, as is evident from the exchange of letters. Some of Einstein's letters were published in the book for the first time in English, and this is particularly welcome in the year of Einstein's centenary.

Throughout the book Infeld portrays many scientists, living and dead, whom

Aims and Scope

The Journal of Biochemical and Biophysical Methods offers researchers a unique opportunity to keep abreast of the development of methods used to solve biological problems. Providing a medium for the rapid publication of research papers and critical, concise reviews concerned either with new methodology, or with the significant modification of existing techniques, the journal will be essential reading for the laboratory worker needing to keep up-to-date with methods, or the specialist interested in method development. The scope of the journal is broad, encompassing all methodological aspects of biochemistry, biophysics

and molecular biology. Although articles should be written in sufficient detail to allow easy verification they should also be intelligible to a broad scientific audience. In addition the journal will publish a section of short notes describing improvements in methods which, though significant, do not warrant a full-length research paper. Short review articles dealing with recent developments in a particular method or technique that are of interest to a broad scientific audience will also be published.

The essence of the journal is high quality and rapid publication.

The following contents of Volume I, Issue I give an indication of the broad scope and authoritative nature of the journal

Determination of small differences in buoyant density of macromolecules by analytical density gradient equilibrium centrifugation

P. Nieuwenhuysen (Antwerp, Belgium)
Rapid pH and μH^+ jump by short laser pulse
M. Gutman and D. Huppert (Tel Aviv, Israel)
The application of Fourier transform infrared transmission spectroscopy to the study of model and natural membranes
D. G. Cameron, H. L. Casal and H. H. Mantsch (Ottawa, Canada)

Chromatographic properties of Sephacryl S-300 Superfine

I. Johansson and H. Lundgren (Uppsala, Sweden)
Human globin chain separation by isoelectric focusing
P. G. Righetti, E. Gianazza, A. M. Gianni, P. Comi, B. Gligioni, S. Ottolenghi, C. Secchi and L. Rossi-Bernardi (Milan, Italy)
Fluorography of tritium-labelled proteins in immunoelectrophoresis
O. Norén and H. Sjöström (Copenhagen, Denmark)
Short note: Automated scanning of ^{14}C on polyacrylamide gel
R. P. Magnusson and A. Jackiw (Bethesda, MD, and Detroit, MI, U.S.A.)

Perspectives in Grassland Ecology

Results and Applications of the US/IBP Grassland Biome Study

Editor: N. R. French

1979. 58 figures. XVII, 686 pages.

(Ecological Studies, Volume 32)

ISBN 3-540-90384-4

In preparation

Contents: Introduction. – Grassland Primary Production: North American Grasslands in Perspective. – Processes Controlling Blue Grama Production on the Shortgrass Prairie. – Analysis of the Response of a Grassland Ecosystem to Stress. – Grassland Biomass Trophic Pyramids. – Patterns of Consumption in Grasslands. – An Ecosystem-Level Trophic Group Arthropod and Nematode Bioenergetics Model. – Factors Influencing Input and Output of Nitrogen in Grasslands. – Simulated Impact of Management Practices upon the Tallgrass Prairie. – Data-Based, Empirical, Dynamic Matrix Modeling of Rangeland Grazing Systems. – Prinzipal Subsystem Interactions in Grasslands. – Index.

Perspectives in Grassland Ecology examines the biomass structure of grasslands in North America and other areas of the world. It compares trophic structure, and describes structure modifications occurring when water and nutrients are artificially supplied. The most important driving variables, processes, and the major functional aspects of production are analyzed and modeled mathematically. Unique in its detailed comparative analysis of the major grassland types, this book will be appreciated by researchers in range science, ecology, agronomy and botany.

Grassland Simulation Model

Editor: G. S. Innis

1978. 87 figures. XXVI, 298 pages

(Ecological Studies, Volume 26)

Cloth DM 49,60; US \$ 27.30

ISBN 3-540-90269-4

Contents: Objectives and Structure for a Grassland Simulation Model. – Abiotic Section of ELM. – A Simulation Model for Grassland Primary Producer Phenology and Biomass Dynamics. – A Mammalian Consumer Model for Grasslands. – Simulation of Grasshopper Populations in a Grassland Ecosystem. – A Simulation Model for Decomposition in Grasslands. – A Grassland Nitrogen Flow Simulation Model. – Simulation of Phosphorous Cycling in Semiarid Grasslands. – Sensitivity Analyses in the ELM Model. – Critiques and Analysis of the Grassland Ecosystem Model ELM.

This model for grassland ecosystems covers abiotic, producer, consumer, decomposer and nutrient cycling aspects. The result of several years' work by a team of scientists, the model was conducted under the auspices of the US/IBP Grassland Biome Study. An extensive field data acquisition program complemented the modeling effort, as did a simulation compiler development effort. The completed model is analyzed for sensitivity, and a critique section evaluates the success of the effort, suggesting ways in which subsequent efforts might be improved.

he met, and in general he speaks about them with kindness. But he has no kind word for Oppenheimer, in an essay written in the last year of Infeld's life and published after his death. The cause of his wrath was a lecture on Einstein given by Oppenheimer in 1965, and which—in the version available to Infeld—was an amazing denigration of Einstein. Point by point, Infeld proved Oppenheimer's distortions, and in the process he lashed out

at him with all the might of his pen. Even the news of Oppenheimer's death, which reached Infeld while he was writing the essay, did not mollify him, because he believed that the saying that one should speak only good of the dead does not apply when referring to a figure belonging to history.

I adhered to this view in writing this review of Infeld's book. □

J. Rotblat is Emeritus Professor of Physics in the University of London, UK.

Journey through relativity

Joe Schwartz

Einstein's Universe. Written by Nigel Calder. Narrated by Peter Ustinov. Produced by Martin Freeth. (BBC-TV: London; WGBH: Boston, 1979.) First UK transmission: 14 March, 1979, BBC-2, 1900 h. Repeated 18 March.

I HAD watched one of Nigel Calder's previous BBC science extravaganzas—*Key to the Universe*—with friends: an immunologist, a developmental biologist and a psychotherapist. The developmental biologist went upstairs, the psychotherapist fell asleep (we didn't wake her), and the immunologist and I discussed immunology. Calder's approach to physics is characterised by a "gosh, isn't science grand" school-boy attitude and in *Key to the Universe*, his taste could be given free rein. Quarks (with colour and flavour), strangeness, hypercharge, charm, were right up his alley. Calder is captivated by the terminology of high energy physics and obviously enjoys the mystery and incomprehensibility of it all. This view is not uncommon among science journalists. James Gorman, a New York writer, confessed last year: "I value physics, not for how well it explains the world, but much as the irreligious loved the Latin mass, for how it sounds."

So I waited for *Einstein's Universe* with some apprehension. Einstein hated obfuscation and mystification. "Since the mathematicians have attacked relativity, I myself no longer understand it", he wrote sarcastically in 1909. The core of his work has long been acclaimed for its simplicity. Special relativity (1905) is based on two simple physical propositions; all steady motion is relative and there are no instantaneous interactions in nature.

General relativity (1916) is built on the simple physical fact that all objects fall at the same rate in a gravitational field.

Einstein is legendary for having been able to extract far-reaching conclusions from these slim physical clues. In the special theory he replaced Newton's metaphysical absolutes of space and time with a material absolute; there are no instantaneous interactions in nature, no signal can propagate faster than the speed of light. In the general theory, Einstein put geometry on a material basis. The validity of Euclidean geometry became a problem for physical investigation, not for abstract contemplation. Experiment would decide whether we live in a Euclidean world where two parallel lines meet at infinity or whether we do not. (We do not.)

Calder's programme was far better than I expected. *Einstein's Universe* is a major improvement over *Key to the Universe* with numerous innovations that need to be developed further. The use of Peter Ustinov as a foil avoids the phenomenon of authoritative talking heads speaking directly to the camera. Moving the set out of the studio and into a live observatory (McDonald) gives more immediacy. The models and animations are quite effective, particularly the curved billiard table. Roger Penrose projects an intensity and seriousness that is a welcome contrast to the usual bland pronouncements from the scientific orthodoxy. And the informal discussion at the end of the programme expressed some of the tone and quality of research work at the frontiers of physical theory.

But it is not enough. I will be greatly surprised if many viewers found their interest sustained for the entire show. The problem lies in the script. Calder concludes the show with an Einstein quote: "The most beautiful thing that we can experience is the mysterious." But Einstein, for whom clarity was paramount, did not mean mystery at the hands of his fellow human beings. He meant the concrete mysteries of nature. The mystery the programme leaves us is a lack of

physical understanding of the astounding results of relativity; black holes, the expanding universe, clocks running slow, $E=mc^2$. We do not know how the theory produces these results or what were the problems for which these results are the solutions. It is Einstein turned on his head: the results of the investigations are seen to be mysterious, not the problems that gave rise to them in the first place.

Wheeler's summary of general relativity is excellent. "Space tells matter how to move and matter tells space how to curve." But how many people will be able to say that they understand what Wheeler means. It is irritating to hear the constancy of the speed of light, the physical basis of the special theory, repeatedly referred to as Einstein's "obsession". The physics has got lost in the whizzing shots of complex machinery, cables, flashing lights and intricate experimental arrangements. If the point is to explain and not to mystify a way has to be found to make the equipment more than a mere spectacle. Einstein actually was quite knowledgeable about experimental work. In 1908 he and a friend Paul Hahich patented a design for a sensitive voltmeter accurate to half a millivolt which was in advance of the instruments of the time.

The striking results of the theory get

BIO-MATHEMATICS Revue de Bio-Mathématique

us in the front door. But once we are there nothing much is shown. Where are the workers in the field, the graduate students, the post-docs. Where are the arguments. Some experimentalists and theorists do not believe in black holes. Where are they. The Ustinov character is an advance but he is too passive. We need a character who can force the explainer to acknowledge that some of the ideas are poorly understood and insufficiently tested. We should see some actual data instead of simply being told that an experiment satisfies Einstein's theory to 1%. The human substance is missing and the presentation of shocks and thrills wears thin half-way through.

Journalists have to dig harder for their stories. They need to use the same

critical sense they reserve for other subjects and apply it to science reporting. A more critical less idolised approach is needed. Einstein recognised this problem himself: "In my view, there is but one way to bring a great scientist to the attention of a larger public; it is to discuss and explain the problems and solutions which have characterised his life work. Otherwise the result is a banal hero-worship based on emotions and not on insight." [Emphasis added.] Science is not more objective and mysterious than any other human social activity. Everyone in science knows this. It is time to start showing it to the public. □

Joe Schwartz is a freelance journalist on leave from the City University of New York.

Foundations of relativity

P. C. W. Davies

General Relativity from A to B. By Robert Geroch. Pp.225. (University of Chicago Press: Chicago and London, 1978.) £8.40; \$11.95.

TEN years ago introductory books on general relativity were a rarity. Since then, advances in the subject and a greater awareness among students that gravity is an intriguing, even bizarre, branch of physics, have stimulated a stream of works appealing to the bottom end of the market. An enormous number of people want an appetite-wetter that will "get them into" gravity without the traditional years of investment in advanced mathematics, and not only so that they can bore dinner guests with virtuoso expositions about black holes. Often more formal treatments do not succeed in communicating the sense of awe and iconoclasm that stems from topics such as total gravitational collapse, event horizons and singularities in spacetime. In addition, mathematically based texts tend to ignore the reader's struggle for sound physical intuition, and depend upon a sort of intellectual osmosis in which feeling for the physics is supposed to slowly and spontaneously filter through the formulae.

Robert Geroch is a man of outstanding international reputation, whose personal contributions to the subject of general relativity are great. He is also a skilful expositor, and has taken enormous trouble to write a book in which the reader starts out from basics. The book is a product of a lecture course given to non-science under-

graduates at the University of Chicago, but it can be read with profit by science specialists who want to acquire a historical and philosophical perspective, to scrutinise the fundamental concepts that underpin the theory of relativity, and to perceive what is a rather specialised branch of physics, with a human face. The text is liberally punctuated by line drawings, some of which might, but should not, frighten the potential reader browsing through the pages.

Part A of the book dwells, perhaps a little too laboriously, on the image of our world as a spacetime threaded by worldlines of matter. To communicate the crucial and fundamental concept of the relativity of motion, much space is devoted to the old and discredited Aristotelian and Galilean concepts of space and time. These sections certainly help to focus the reader's attention on the basic issues at stake, but carry the danger of making Aristotle seem more reasonable than Einstein. There is a sense in which relativity is equally as elegant and natural as the everyday, intuitive view of space and time, but a historical approach to the subject does not always do it justice.

The greater part of the book (Part B) gets to grips with general relativity in its full splendour. Professor Geroch adroitly guides the reader through the geometrical basis for gravity without burdening him with elaborate formalism or needless jargon. Every new concept is strongly rooted in concrete physics. Meter sticks, clocks, light signals, records—people—inhabit the author's models, observing and measuring all sorts of phenomena. Great emphasis is laid on physical meaning and consistency, on asking and answering exactly what is meant by distance, interval, and so forth. It is quite the most elaborate discussion of the funda-

mental aspects of relativity that I have encountered in a non-specialist book.

The price paid for this admirable but extended devotion to "getting it straight" is that Einstein's actual theory does not surface until three-quarters of the way through the book, and when it does, perhaps inevitably for a book at this level, it is largely in the form of analogy. This leaves very little room for applying the theory to anything exciting, but a mandatory chapter on black holes is included. Readers who have taken the effort to get this far will find that the weird and wonderful properties of these entities can in fact be understood in a straightforward way now that the spacetime geometry concept has been so thoroughly well explained. Professor Geroch explicitly excuses himself from

Einstein expounding to Ramsay MacDonald

what he calls "gee-whizzes", but still manages to convey the immensely engaging nature of the black holes subject. I was a little disappointed not to see an extensive discussion of singularities, and also the big bang and cosmology, but there is always the possibility of a *C to D* sequel.

In summary, *General Relativity A to B* is one of the few books that treats the foundations of the theory of relativity seriously and in elaborate detail, at the non-specialist level. It cannot be read, however, without effort and commitment. The index is rather sparse and the price a shade too high, but otherwise it is a nicely produced book that in spite of its narrow scope illuminates many grey areas of spacetime physics. □

P. C. W. Davies is Lecturer in the Department of Mathematics at King's College, University of London, UK.

obituary

Margaret Mead, 1901–1978

MARGARET MEAD died on 15 November 1978 just a month before her 77th birthday. Thus ended a unique career. Boundlessly energetic and phenomenally productive (her bibliography runs to nearly 4,000 items), alert to every new development in the humane sciences, sensitive to urgent social issues and with a talent for working with and through others, she achieved a world-wide fame.

Her place in the history of American anthropology is assured; for she played a decisive part in its transformation from a narrow academic specialism into a modern humane science with world-wide interests. But she will also have a place in the social history of the United States for her catalytic influence on the development of educational and moral ideals and values after World War II. Field work, she often proclaimed, was the 'living stuff' of anthropology and she made over 20 field trips between 1925 and 1975. But in between spells of writing, teaching and organising research, she also travelled indefatigably in America and abroad, to lecture, to preside at conferences, to advise academic bodies or governmental agencies, and so on. But whatever the occasion might be, she always took her stand as an anthropologist, drawing attention to the many alternatives mankind had invented for dealing with the common problems of personal and social life.

Margaret Mead was born on 16 December 1901 in Philadelphia. As her father was a Professor of Economics and her mother an early student of sociology, she could say with pride, in her autobiography *Blackberry Winter* (1972), that she grew up in a 'social science' family. To their influence was added that of her grandmother, whose example inspired the ideals which made Dr Mead essentially an educator.

Dr Mead came into anthropology by chance. After a miserable year at De Pauw University she moved to Barnard College in New York in 1920. While completing her degree in psychology she was drawn into Franz Boas's circle. What most influenced her, however, was her friendship with Ruth Benedict, Boas's assistant, which was to last a lifetime of close collaboration. Anthropology was in a ferment just then,

Functionalism, with its emphasis on fieldwork and the analysis of the internal integration of primitive societies, had been launched in England. In America the complementary 'configurationalist' movement, later to come to brilliant fruition in Benedict's *Patterns of Culture* (1934) was under way. And in the background loomed the figures of Freud, Jung and later Piaget. Mead took something from each to form her guiding principle that culture shapes character, is learned and is lived by individuals.

Mead's fieldwork began in 1925 with her study of a group of adolescent girls in Samoa. She found that unlike American girls, they suffered no emotional crises in the transition to adulthood, and she attributed this to the benign sexual mores and family system of Samoans. Addressing herself to the general public in her deliberately 'novelistic' best-seller *Coming of Age in Samoa* (1928) she drew the moral. A new image emerged of anthropology as a science of public enlightenment. Later, reacting to straight-laced anthropological criticism, in a conventional monograph, and journal articles, she presented the technical anthropological and psychological data on which she based her book; and she did likewise with all her subsequent fieldwork.

Dr Mead's next field study, shared

with her second husband Reo Fortune (her first was the archaeologist Luther Cressman) took her to the lagoon-dwelling Manus of the Admiralty Islands, New Guinea. Here, supplementing ethnographic observation with ingenious psychological tests, she found that contrary to some psychologists' theories children were not naturally animistic. A puritanical, competitive culture made fearful animistic adults of them. Her second popular book, *Growing Up in New Guinea* (1931) was another best-seller.

In 1931, after a depressing interlude in a disintegrating Omaha community (described in Mead's *The Changing Culture of an Indian Tribe*, 1931) they returned to New Guinea. Three strikingly different tribes were visited. There they were joined by Gregory Bateson, fresh from his Iatmul field work. Discussions with him crystallised an hypothesis that cultural patterns incorporated different psychologically identified temperamental types. Mead's *Sex and Temperament in Three Primitive Societies* (1935) developed this hypothesis to explain the startling contrasts in the norms of sexual identity and behaviour in these three tribes. The book, like its predecessors, was severely criticised by some anthropologists. But her argument that what are now called 'gender' differences are culturally inculcated not biologically determined, brilliantly anticipated the position vigorously maintained by women anthropologists today.

Mead elaborated this theme in lectures and articles in both popular and learned journals. Fourteen years later she refashioned it in *Male and Female* (1949), her most influential book. Comparing observations in seven non-Western cultures with the American scene, she examined the cultural variations in the roles of men and women in the reproductive process and in the socialisation of children, and related this to the way the oedipal conflict is resolved, thus drawing attention to the significance of the father in character formation. Here again she anticipated what has become a topic of major research activity among psychologists, anthropologists and some behaviour biologists.

Breaking with Fortune in 1936, she

married Bateson; and this partnership led to the field study in Bali (1936–1939) which they claimed, with some justice, to have been a major advance in anthropology.

In Bali they were faced with a complex oriental civilisation very different from primitive New Guinea, though, as before, their concern was primarily with culture-learning, the ways as they put it 'living persons embody their culture'. Their main innovation was the huge and minutely detailed photographic documentation that foreshadowed the post-war rise to prominence of the ethnographic film. Their fieldwork concentrated on interpersonal relationships and interactions, particularly of parents and children in the context of child-rearing and socialisation processes, that were central to Dr Mead's interests. Her imaginative psychological commentary on the photographic record in their book *Balinese Character* (1942) and in other publications, provoked controversy but also stimulated new approaches in ethnological psychology. The 'anthropology of the body' is a new field of research concerned with problems of the cultural specification of postures, gestures, and body images and processes, and it owes much to the pioneering work of Bateson and Mead.

World War II brought unexpected challenges to American anthropologists. Dr Mead worked with various governmental agencies concerned with the war effort. But most important was the leading part she played in the international team of specialists assembled by Ruth Benedict to compile reports on the 'national character' of the belligerents. Field work being ruled out, they resorted to studying 'culture at a distance', through interviews with immigrants and analysis of literary, film and archival sources. As the publications of the team showed—notably Benedict's celebrated study of the Japanese, *The Chrysanthemum and the Sword* (1946) and Mead's passionate morale-booster *And keep your Powder Dry* (1943)—the method was remarkably effective, so much so that the project was continued until 1951 (with 120 participants!) under the auspices of Columbia University.

The war and especially, by Mead's own account, the shock of Hiroshima, brought home to her the urgent need for a new social and moral vision in western, especially American society. The war had broken down the cultural isolationism which she had helped to expose in her popular books. It had also, she learned, produced unprecedented changes in New Guinea. This led her, in 1953, to return to Manus, accompanied by a student couple.

She found the community completely transformed. Partly owing to the war and to Australian government agencies, but mainly to the charismatic leadership of one local man, the people had abandoned their entire traditional way of life and were rapidly adopting western institutions and ideals. Examining these changes in her *New Lives for Old* (1956) Dr Mead concluded that a unanimous primitive community, once convinced of the desirability of western cultural ideals and institutions, can, given inspired leadership, radically change its way of life in a generation. Thenceforth she advocated the wholehearted support by anthropologists of speedy westernisation in primitive communities with the right leadership and aspirations. She visited the Manus thrice again thus keeping benevolently critical track of their progress in self government, in family life, and in personality development, until 1975.

Watching Manus inspired in Dr Mead an abiding concern with the problems of changing society. Thus orientated, between 1953 and 1975 she also visited the other groups in which she had earlier worked, as well as the growing urban centres in New Guinea. Preoccupied now with the problems of reconciling continuity and change in cultural development (as in her book *Continuities in Cultural Evolution*, 1964) she travelled widely in America, the Caribbean, Europe and the Southern Hemisphere, often enough to participate in academic or policy-making activities, and so to enlarge her understanding of urgent world issues. The key to a more enlightened and humane future, she believed, lies in the way the culturally specified relations of successive generations of grandparents, parents and children, where character is shaped and culture is transmitted, are managed. She stressed in particular the models of the alternatives anthropology has revealed for handling the universal problems of intergenerational conflict.

Never hiding her light under a bushel, Margaret Mead yet disdained pretensions to originality. On the contrary she constantly stressed her indebtedness to others, friends, famous scholars, students and predecessors. But as the long list of visiting professorships, honorary degrees, other academic distinctions, and awards and prizes conferred on her testifies, the pre-eminence of her scientific achievements, her devotion to America and her dedication to the ideals of human betterment were widely esteemed. A phenomenon like Margaret Mead could perhaps not have emerged in any other country than modern America. From her base in the American Museum of

Natural History, where she worked, and taught from the time of her appointment as an assistant curator in 1925 to the end of her days, she exercised a decisive influence both on the development of the social and human sciences in America and elsewhere, and on American educational, and moral values and cultural ideals. But she will undoubtedly be best remembered, as she would herself have wished, as one of the most creative anthropologists of this century.

Meyer Fortes

Bernard Halpern

BERNARD N. HALPERN, one of the first workers on antihistamines, died in Paris on 23 September 1978, after suffering for several years from an incurable and painful illness.

Born in 1904 in Russia, Bernard Halpern came to France after some very difficult childhood years, to complete his advanced studies for a degree of Doctor of Medicine (1936). In order to study, he worked for several years as a technical assistant in the physiological laboratory at the Ecole pratique des hautes Etudes, under the direction of J. Gautrelet.

In 1937, Halpern took over as director of the pharmacodynamic research laboratory of the Société Rhône-Poulenc. He left this position in 1945 to join, as a research worker, the Centre National de la Recherche Scientifique and to direct the Pasteur-Vallery-Radot laboratory at the Broussais hospital. In 1949, he was nominated Director of Research at the CNRS; ten years later, he added to these functions those of Director of Laboratories at the Ecole pratique des hautes Etudes. In 1961, Halpern was awarded the Chair of Experimental Medicine at the Collège de France, a chair formerly held with distinction by Claude Bernard, and was elected a member of the Académie des Sciences in 1964.

After early work with J. Gautrelet on the action of snake venoms, Halpern devoted himself from 1942 onwards to the study of synthetic compounds behaving as antihistamines, at the Rhône-Poulenc laboratories.

This research topic was, it must be said, initiated some years earlier (1937) by G. Ungar, J.-L. Parrot, and D. Bovet, who used in their experiments compounds belonging to the sympathomimetic and sympatholytic groups obtained from E. Fournau's laboratory at the Institut Pasteur. In the same year (1937), D. Bovet and A. M.

Staub had detected the same antihistamine properties in thymoxyethyl-diethylamine (929 F) and, some years later, the study of some derivatives of phenylethylenediamine and aminopyridine showed equally favourable properties. As a result of other work by A. M. Staub (1939), Halpern proved in 1942 the relatively high antihistamine effect of N-(2-dimethyl aminoethyl)-N-benzylaniline or Antergan on spasms in unstripped muscles and pointed out the possible use of this compound in human therapy.

In 1944, another compound appeared, Neoantergan, equally suitable for human application which, while chemically similar to Antergan, was more active (Bovet *et al.*, 1944). Still more important appeared to be the N-alkylamine derivatives of phenothiazine, among which Halpern noted the efficacy of Phenergan (1946). It is well known that, apart from its antihistamine effects, this compound was found by doctors to be a psychodepressant and formed the starting point for many neuroleptic derivatives currently used in psychiatry.

From 1950, following research by Jancsó, the work of Halpern and his collaborators took another direction: the functional study of the reticulo-endothelial system (RES). Profiting from the granulopoietic activity of this tissue, they investigated the removal from the blood of various colloids as a function of time. These data once established, the authors found that stimulation of the RES increases the level of immunity of the organism against various infections.

In 1959, Bernard Halpern showed, for the first time, that administration of BCG increases the resistance of the organism to malignant tumours.

In 1964, he described the outstanding immuno-stimulatory properties of *Corynebacterium parvum* on the reticulo-endothelial system. This effect is shown by the increase in the phagocytic index of macrophages and by the increase in liver volume and of splenic cells. Later, Halpern established that the administration of *Corynebacterium parvum* inhibits the development of grafted malignant tumours and their propensity to metastasis. In May 1974, he chaired the first international conference on *Corynebacterium parvum* and its use in oncology, a conference which has led us to revise our ideas of the relations between the host and the malignant tumour. *Corynebacterium parvum* has been employed for several years in human therapy in the treatment of cancers in combination with antimetabolic chemotherapy and the results of this method appear promising.

G. Valette

W. O. James

PROFESSOR WILLIAM OWEN JAMES, FRS, who died on 15 September 1978 will be remembered as one of the leading British plant physiologists of this century.

The major part of his academic life as a scholar, teacher and author (from 1929 to 1958) was spent as Demonstrator and then Reader in the Department of Botany at Oxford University. He was elected to the Royal Society in 1952. Latterly from 1958 until his retirement in 1967 he was an innovative Head of Botany at Imperial College, London at a time when the college was rapidly expanding.

During his professional life of over 50 years, W. O. James made many distinguished contributions to several different fields of plant physiology including photosynthesis, mineral nutrition, anaerobic and aerobic respiratory metabolism, alkaloid metabolism and to the understanding of the function of subcellular organelles. His endeavour was always to discover and understand the biochemical events responsible for the physiological functions of plants and to account for these responses quantitatively. He wrote with exceptional clarity and his many scientific papers and several books reflect his scholarly analysis of plant physiological phenomena and his imaginative application of contemporary experimental techniques as aids in understanding them. He retained an enthusiasm for plant biology to the end of his life and was always particularly delighted to hear of progress in the several areas of research in which he himself had been involved.

W. O. James brought to the study of the many-faceted problems of the physiology of plants incisive thought and great care in the design and execution of experiments. These qualities were already manifest in his first paper on the external factors affecting photosynthesis reporting his studies as a graduate student under F. F. Blackmann in Cambridge in the mid 1920s. James demonstrated departures from the limiting factor form of the curve for photosynthesis and explained why they were to be expected. During his postdoctoral years, spent from 1925 in V. H. Blackmann's unit of Plant Physiology at Rothamsted, his interest in mineral nutrition of plants, particularly of potassium, developed, and on his move to Oxford in 1927, the effects of potassium deficit on extractable enzyme activity and respiration rate were among the first problems he tackled. He soon realised that useful interpretation of the experimental effects of mineral nutrition on plants was severely limited by lack of under-

standing of the respiratory processes occurring in normal plants and he and his associates turned their attention to the study of plant respiration.

It is for his contributions to our understanding of plant respiration that James will probably be best remembered. His group in Oxford carried out some of the first definitive work on glycolytic systems in plants and in the early 1940s demonstrated unequivocally that pyruvate was produced from fructose diphosphate in extracts of barley. Later they examined the enzyme systems involved using the phosphorylated intermediates and cofactors which had recently become available commercially, and showed the key enzyme enolase was present in barley sap.

His group published detailed descriptions of the respiratory characteristics of several different plant tissues including leaves, roots and embryos and sought to explain their *in vivo* respiration quantitatively in terms of the activity of enzymes which could be isolated from them. It was demonstrated, for example, that sugar lost from carrot tissue during a period in N_2 could be accounted for entirely by alcohol and CO_2 production. In attempts to explain the terminal oxidation processes in plants whose respiration was differentially inhibited by specific respiratory inhibitors, James and his associates also devoted considerable attention to the examination of soluble and insoluble plant oxidases. Much useful detailed information about the distribution and activity of the variety of plant oxidases was assembled, although no convincing evidence that any oxidase other than cytochrome oxidase plays a major role in plant respiration has yet emerged. H. Beevers in James' laboratory in the late 1940s first examined the exceedingly rapid cyanide-insensitive respiration of the *Arum spadix* and later the Oxford group were the first to show the location of this activity in isolated mitochondria. James' years of study of the respiratory processes in plants culminated in the publication of his book *Plant Respiration* in 1953, hailed as a scholarly summary of a whole epoch of plant respiratory studies.

During his years in Oxford, in addition to his research activities, James also taught plant physiology to several generations of undergraduates and, during the second World War, was a prime mover in the Oxford Medicinal Plants Scheme. The objective of the scheme was to supply medicinal drugs by extracting them from natural plant sources. Many of these drugs were alkaloids and in addition to improving methods for their extraction and

analysis, his group obtained much fundamental information about the synthesis and internal concentration of alkaloids in cells.

Shortly before his move to London, James' group had been amongst the first in the world to isolate active mitochondria from plants and study their oxidative and phosphorylative capacities. The group had also begun to use the new techniques becoming available for the examination of the ultrastructure of cell organelles for James had the vision to see the potential of structural studies in understanding intracellular metabolic processes. At Imperial College he set up a Unit of Analytical Cytology where electron microscopists and biochemists worked together to isolate, purify and characterise subcellular plant organelles. New electron microscopical techniques were developed to monitor the purity and integrity of the isolated organelles used in a continuation of the studies of mitochondria to localise cellular respiratory activities. Later plant nuclei, ribosomes and chloroplasts were examined and the group were the first to publish methods for the isolation of structurally intact chloroplasts and also plastoglobuli and grana from them.

In addition to introducing the study and teaching of analytical cytology of plant cells, James also initiated and fostered the development of new sections of the department at Imperial College to study plant taxonomy, palaeobotany and nitrogen fixation. He guided and encouraged those who shared his enthusiasm for all aspects of plant biology and by example and positive criticism showed the high standard of scientific expertise required to gain a true insight into plant function.

In addition to publishing numerous papers reporting his own research findings, for many years James was a co-editor of *New Phytologist* and a member of the editorial panel of *Endeavour*. His uncluttered literary style also contributed to his skill as a good writer of school and university texts and semi-popular articles and books. All his publications were characterised by the high standard of the beautifully presented and appropriate illustrations. For almost 50 years his now classical text *Introduction to Plant Physiology* (first edition 1931, seventh edition 1972) has been the introduction for successive generations of schoolchildren and undergraduates to this field. In the preface to the fourth edition he looks forward to the time when the reader of his book will take part in finding some of the answers to unsolved physiological problems: indeed there have been

many whose initial interest was aroused by his text and who have gone on to make their own contributions as professional plant physiologists. His *Introduction to Plant Biology* is still used as 'the bible' for school and university courses. His amusing book *Background to Gardening* became a best-seller. After his retirement he published *Cell Respiration* (1971) which gives a comprehensive account of the respiration of the whole range of living cells.

James' distinguished contributions as a scientist were made despite recurrent ill-health throughout his life. All who knew W. O. James and his wife recognise the magnificent supportive role she played throughout his career. His many former colleagues now working in all parts of the world have cause to be grateful to W. O. James for his scholarly example.

R. M. Leech

Francis Aylward

PROFESSOR FRANCIS AYLWARD who was Professor of Food Science in the University of Reading from 1968 to 1976 died on 28 September 1978, aged 67. A memorial service for him was held in Westminster Cathedral on Thursday, 7 December.

After graduating at Liverpool University with first class honours in chemistry, he remained at Liverpool studying lipid chemistry under Hilditch (whose school was of international repute) and obtained his PhD. His subsequent contribution to lipid chemistry and biochemistry was recognised by the award of a DSc in 1958.

Francis began his scientific career by holding research fellowships at the Hannah Dairy Research Institute and Johns Hopkins University. The war years were spent with ICI Ltd. In 1947 he was appointed Head of the Department of Chemistry and Food Technology at the Borough Polytechnic. It was at this time that it began to be recognised, largely as a result of food research carried out in USA and UK, that a substantial and systematic body of knowledge had accumulated, and the time had arrived for food technology to be taught as a discipline particularly to provide the food industry (which was rapidly expanding and moving from a craft based to a scientifically oriented industry) with its scientific manpower. The Borough Polytechnic was one such teaching institution that recognised this need, and under Francis's able and progressive leadership the food technology element of his department grew and flourished.

Though still retaining his interest in lipids he began to take a greater interest in the role of food technology in relation to nutrition and food supplies.

This led naturally to his appointment in 1960 to serve for two years as FAO Adviser on Food and Nutrition to the Government of Ghana, and for the period 1961-62 as Head of the newly created Department of Biochemistry, Nutrition and Food Science at the University of Ghana. From that time he developed a major interest in nutrition in relation to national and international food problems. From Ghana he moved to Poland and during 1962-65 he was Director of the Polish Food and Nutrition Project supported by the UN special fund.

In 1965 he returned to Britain as Director of the Fruit and Vegetable Preservation Research Association, Chipping Campden. Then in 1968, following the retirement of Professor Crossley as Professor of Dairying and the decision of Reading University to broaden the interests of the department to cover food science, Francis was appointed its first professor. In many ways this was an apt and fortunate appointment. Francis believed that institutes of higher education have a duty to assist developing countries, and this view agreed well with the tradition of Reading's Faculty of Agriculture. He obtained a substantial grant from the Leverhulme Foundation which permitted him to support two Senior Fellows and with their help he built up a large postgraduate school of food science—the largest in Europe—drawing most of its students from developing countries.

While at Reading he continued to act as consultant on behalf of organisations of the UN. This work was complementary to his service as Chairman of the University's Overseas Service Committee. Within the UK he was an active member of the Food Group of the Society of Chemical Industry. He was a member of the Food Additives and Contaminants Committee of the Ministry of Agriculture, Fisheries and Food. After retiring from his University post he continued to put great effort into helping with nutrition programmes overseas. He was appointed a member of the UN Advisory Group on Nutrition and was engaged in co-operating with UNEDO in regional services of food industries in the developing countries.

The heavy demands his career made on his time were not allowed to prevent him from playing an active role in the Roman Catholic Church, and recognition was given in 1951 when he was appointed a Knight of St Gergory.

With the untimely death of Francis Aylward, we in food science and technology have lost not only a highly respected colleague, but a friend of great warmth and personal kindness.

E. Rolfe

APPOINTMENTS VACANT

UNIVERSITY COLLEGE OF NORTH WALES

Applications are invited for the post of

LECTURER IN AGRICULTURE

Applicants should have a degree in Agriculture, Agricultural Science or a related discipline, together with appropriate postgraduate experience in grass production and utilisation.

The appointment, to commence on September 1, 1979, or any earlier date by agreement, will be to the University's Lecturer Scale: £3,883 to £7,754 p.a. (under review).

Applications (two copies), giving details of qualifications and experience, together with the names and addresses of three referees should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DG, from whom further particulars may be obtained.

Closing date for applications. April 1979 24(A)

UNIVERSITY OF READING

LECTURESHIP AT THE NATIONAL COLLEGE OF FOOD TECHNOLOGY

Applications are invited for a Lectureship, tenable at the National College of Food Technology, Weybridge, from persons with qualifications and experience in applied microbiology preferably of particular relevance to the food industry. The successful candidate will be expected to contribute to teaching at undergraduate and postgraduate levels and develop an experimental research programme. Opportunities for research are available in all aspects of food microbiology.

The appointment will date from October 1, 1979.

Further information may be obtained from the Registrar (Room 214, Whiteknights House), The University, Whiteknights, Reading RG6 2AH, by whom applications should be received not later than April 30, 1979. 49(A)

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF BIOCHEMISTRY SCHOOL OF BIOCHEMICAL AND PHYSIOLOGICAL SCIENCES RESEARCH ASSISTANT/ FELLOW—SYNTHETIC ORGANIC CHEMISTRY

Synthesis of Novel Antibiotics

Applications are invited for a research assistant/fellow to participate in a programme of work directed towards the synthesis of novel antibiotics. The vacancy will suit an organic chemist with a Ph.D. degree but chemistry graduates wishing to move into the area of bio-organic chemistry are encouraged to apply.

The position, which in the first instance is for a ONE YEAR appointment, is available immediately.

Starting salary up to £4,382 per annum, depending on qualifications and experience. USS benefits.

Applications giving date of birth, curriculum vitae and the names and addresses of two referees should be sent as soon as possible to Mrs P. Vaughan-Smith, The University, Southampton SO9 5NH, quoting reference 1057/R/N 48(A)

UNIVERSITY OF LEICESTER

LECTURESHIP IN BIOCHEMISTRY

Applications are invited for a Lectureship in the Department of Biochemistry. It is likely that preference will be given to candidates with a strong background and current interest in chemical and physical aspects of Biochemistry. Excellent research facilities are available. Candidates should be prepared to take up their duties from October 1, 1979.

Salary according to qualifications and experience on the scale £3,883 to £7,754 (under review) with superannuation benefits.

Further particulars from the Registrar, University of Leicester, to whom applications on the form provided should be sent by April 27, 1979 56(A)

ST GEORGE'S HOSPITAL MEDICAL SCHOOL (University of London) POSTDOCTORAL RESEARCH ASSISTANT

required for an M.R.C. three-year project working with Dr. J. A. Firth in the Department of Structural Biology on the mechanisms of trans-placental transport of hydrophilic molecules. Applicants should have a background in Mammalian Physiology and be interested in the application of ultra-structural tracer methods, experience in electron microscopy is desirable but not essential. Salary scale £3,883: £4,133: £4,382 (under review) plus London allowance £450 p.a. Further particulars and application forms available from the Establishment Officer, St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE. 99(A)

IMMUNOCHEMISTRY UNIT DEPARTMENT OF BIOCHEMISTRY UNIVERSITY OF OXFORD TECHNICIAN GRADE 3

A vacancy exists for a technician with experience in general biochemical techniques to work in the field of protein chemistry. Education to O.N.C. level or equivalent is required. Salary on the scale £2,688 to £3,060 p.a. Applications as soon as possible, including the names and addresses of two referees, should be sent to:

The Administrator,
Dept. of Biochemistry,
South Parks Road,
Oxford OX1 3QU 34(A)

INSTITUTE OF CANCER RESEARCH There is a vacancy for a **TECHNICIAN** to work in the Radiotherapy Research Laboratories at Sutton in a research programme on *in vitro* tests for the sensitivity of human tumour cells to cancer chemotherapeutic agents. The work involves specialised tissue culture techniques as well as some laboratory animal work with xenografted human tumours. Experience in pharmacology would be an advantage. The appointment will be on the Technician scale which starts at £3,261 per annum plus London Allowance of £354 per annum. Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 14 Sumner Place, London SW7 3NU, quoting ref 301/B/62. 19(A)

POSTDOCTORAL POSITION

available immediately for research in the biosynthesis and assembly of basement membranes. Previous research experience with proteins and/or carbohydrates desirable. Experimental techniques include cell culture and somatic cell hybridization. Salary \$12,000, renewable. Send curriculum vitae and two letters of recommendation to Dr Albert E. Chung, Department of Biological Sciences, University of Pittsburgh, Pa., 15260, U.S.A. An Equal Opportunity/Affirmative Action Employer 54(A)

Laboratory SCIENTIFIC OFFICER required as soon as possible for work on a three-year research project, supported by the Medical Research Council, examining the effect of steroids on experimental and human immune complex disease. Techniques used will include basic immunological methods, analytical ultracentrifugation, tests of macrophage function and electron microscopy. Salary for qualified Laboratory Scientific Officer not less than £3,261 plus £354 London Weighting. Apply in writing, stating age and giving details of qualifications and experience, to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, quoting Ref R.U.1 47(A)

INSTITUTE OF CANCER RESEARCH TECHNICIAN or JUNIOR TECHNICIAN required for the electron microscope department at the Chester Beatty Research Institute, Fulham Road, London, SW3. Experience in a biological electron microscope laboratory is desirable but candidates with experience in biochemical techniques or histopathological methods will be considered. The salary will accord with M.R.C. scales in the range £1,905 to £4,680 per annum plus £354 per annum London Allowance. Apply in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 14 Sumner Place, London SW7 3NU, quoting ref 301/B/61 18(A)

The Gambia

Assistant Director (Research and Specialist Services)

Department of Agriculture Up to £9,980

Candidates aged between 30 and 50 should hold a degree in Agriculture or related subject and have at least ten years experience of agricultural research work on sub-tropical crops. They should also have some knowledge of administrative procedure in a Government Department of a developing country. Duties will involve co-ordinating the planning and implementation of research and specialist services programmes.

Salary includes a substantial tax-free allowance paid under Britain's overseas aid programme. Basic salary attracts 25% tax-free gratuity.

Benefits include free passages, paid leave, children's holiday visit passages and education allowances, appointment grant and interest-free car loan.

The terms on which civil and public servants may be released if selected for appointment will be subject to agreement with their present employers.

For full details and application form write quoting MD/214/NA

Crown Agents

The Crown Agents for Overseas Governments and Administrations, Recruitment Division, 4 Millbank, London SW1P 3JD 6(A)

UNIVERSITY OF
NEWCASTLE UPON TYNE
DEPARTMENTS OF PATHOLOGY
AND MEDICAL STATISTICS
JUNIOR
RESEARCH ASSOCIATE

Applications are invited from honours graduates, or prospective honours graduates, in the biological sciences for a post as Junior Research Associate to assist in a research project investigating cell proliferation in the gastrointestinal tract. The work, which is sponsored by the Cancer Research Campaign, will involve cell kinetic and other experiments on hyperplastic and neoplastic gut in rodents. The post is available for three years starting on August 1, 1979 or as soon thereafter as can be arranged. Commencing salary £3,384 per annum on the National Range 1B scale. The successful candidate will be expected to enrol for a higher degree.

Further particulars may be obtained from Dr A. J. Watson, Department of Pathology, University of Newcastle upon Tyne, NE1 7RU, (0632 25131 Ext 445) to whom applications giving full curriculum vitae and the names of two referees should be sent by April 30, 1979. 22(A)

QUEENSLAND INSTITUTE
OF MEDICAL RESEARCH
MOLECULAR
PARASITOLOGIST

Scientists with substantial post-doctoral experience in immunology or molecular biology of parasites are invited to apply for the post of head of a parasitology unit. Current interests include laboratory studies in helminths and protozoa of medical importance, together with the application of modern technology in an epidemiological context. The Institute as a whole has commitments in the fields of infectious disease, oncology, molecular biology and genetics. There are currently some collaborative programmes in the Asian and Pacific regions and participation therein of the appointee will be encouraged. Appointment is initially for five years, renewable, with salary in the range \$A16,322 to \$A20,405 per annum. Applications stating full personal and professional details plus the names of at least two professional referees should be forwarded to Dr C. Kidson, Director, Queensland Institute of Medical Research, Bramston Terrace, Brisbane, 4006, Australia by April 20 59(A)

The Research Organization of an internationally recognized European Pharmaceutical Group located in Paris requires a

SENIOR CARDIOVASCULAR
PHARMACOLOGIST

To join its Department of Biology. The high success rate and rapid growth of this pharmaceutical group is related to the quality of people they employ and their continued commitment to research and development.

For this key position in the Cardiovascular Group we require a professional and highly motivated scientist who will be responsible for various projects within the group and should also be able to conduct independent research programmes.

Applicants can be either male or female and should have relevant post-doctoral experience (a maximum of five years). It is essential that the candidate should have experience of the pharmaceutical industry.

A realistic salary can be expected and relocation assistance will be available with other financial benefits.

All applications will be treated in the strictest confidence and should be sent directly to "Nature", c/o Box No 58(A), 3 Dymers Buildings, Holborn, London EC1N 2NR. 58(A)

GRADUATE OR POSTDOCTORAL Research Assistant required for 1½ years in the Department of Microbiology for an M.R.C. research project on cytomegalovirus immunovirology. Laboratory experience in virology essential. Applications, with full curriculum vitae and the names of two referees, to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. M.C.2 9(A)

Research Archivist

As one of the largest pharmaceutical companies, Hoechst operates on a world-wide scale and the UK Research Laboratories play an integral part in the company's activities. At our new Research Laboratories at Milton Keynes, Bucks, we have a challenging vacancy for a Research Archivist.

This involves responsibility for maintaining a central archive for all laboratory data and providing information services to a group of multi-disciplinary Scientists. It offers an ideal opportunity for an Information Scientist or Graduate Scientist with information services experience to start a career.

The ideal candidate will be familiar with handling questions in organic chemistry.

This appointment carries a good salary, with at least four weeks holiday a year. Benefits include flexible working hours, free private health scheme, subsidised restaurant meals, excellent sports and social facilities. Generous relocation assistance will be provided if applicable.

Please write or telephone for an application form to:
Mr. A. Forrest, Personnel Department, Hoechst UK Limited,
Walton Manor, Walton, Milton Keynes, Bucks.
Tel: Pineham 5088.

2(A)

Hoechst

INSTITUTE OF CANCER RESEARCH: JUNIOR TECHNICIAN required for the Department of Molecular Biology, Chester Beatty Research Institute, Fulham Road, London SW3, in the general field of protein chemistry. The successful candidate will assist in the isolation and characterization of proteins and peptides. Applicants should have at least 2 'A' levels in Mathematics, Physics or Chemistry. Salary in scale £2,370 to £3,015 p.a., plus London Allowance of £354 p.a. Applications in duplicate, with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting Ref 301/B/63. 66(A)

MEDICAL
RESEARCH COUNCIL
RESEARCH ASSISTANT

(Technician/Research Officer)
Salary scale £3,261 to £4,902

The M.R.C. Clinical Psychiatry Unit requires a Psychologist or Social Science Graduate for 3 years to join a small team working on clinical and psycho-physiological studies which include suicide, depression, schizophrenia and expressive movements in psychiatric disorders. The job entails psychological testing and previous clinical experience is necessary. There will be opportunities for training in research methods, and the person appointed will be encouraged to accept individual responsibility for specific aspects of the research projects. Starting salary will depend on previous research experience. The post becomes vacant on June 1, 1979.

Applications to the Director, M.R.C. Clinical Psychiatry Unit, Graylingwell Hospital, Chichester, Sussex PO19 4PQ, enclosing curriculum vitae and the names of two referees. Closing date for applications: April 20 78(A)

INSTITUTE OF CANCER RESEARCH: TECHNICIAN required at the Sutton, Surrey laboratories for work with mammalian cell culture applied to radiobiology. Applicants should have a degree, H.N.C. or equivalent in a relevant subject. Experience in cell culture methods would be an advantage but is not essential. Salary in range £3,261 to £4,680 per annum plus London Allowance of £354 per annum (M.R.C. Technician scales). Applications in duplicate with the names of two referees should be sent to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting ref. 301/B/59. 21(A)

UNIVERSITY OF DURHAM
DEPARTMENT OF CHEMISTRY

Applications are invited for the post of

SENIOR DEMONSTRATOR

In the Department of Chemistry from October 1, 1979. The main duties will be to help with the practical teaching of ORGANIC CHEMISTRY, with tutorials for second and third year students, and to carry out research. An interest in some branch of organofluorine chemistry or polymer chemistry (preparative or structure and bonding by means of photoelectron spectroscopy) and a willingness to join existing groups working in these fields would be an advantage. There will be opportunities for the person appointed to give some lectures.

The appointment will be for three years. Initial salary in the range £3,384 to £4,631 per annum (under review) on Scale 1B or 1A, depending on qualifications, with membership of USS.

Applications (3 copies) naming three referees should be sent by April 18, 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. 25(A)

THE OPEN
UNIVERSITY

Faculty of
Science

Biophysics Research
Fellow—Oxford

Applications are invited for the post of Research Fellow to assist in the study of the structure and transparency of the corneal stroma by a variety of biochemical and biophysical methods working with Professor G. F. Elliott at the Biophysics Research Group, Oxford Research Unit. Techniques used in the laboratory include X-ray diffraction, microelectrode measurements and gel electrophoresis and computer experience would be useful. The post would suit a physicist or physical chemist interested in biology or possibly a physically-minded physiologist.

The post, funded by a grant from the U.S. National Eye Institute is available for three years from April 1, 1979. Salary within the range £3,883 to £5,387 p.a. on the Research Fellow Grade 1A scale according to experience.

Application forms and further particulars are available, by postcard request please, from The Recruitment Office (JD/3796/1), The Open University, P.O. Box 75, Walton Hall, Milton Keynes MK7 8AL or by telephone from Milton Keynes 83868 (24 hour answering service). Closing date for applications: March 28. 3(A)

PLANT PATHOLOGIST — CEREAL CROPS

(109-031-003)

Salary up to \$34,045 depending on experience

Ref. No: 78-RES-73 (N)

Agriculture Canada

Charlottetown Research Station — Charlottetown, P.E.I.

The Public Service of Canada has an immediate requirement for a scientist to conduct a research program in plant pathology with an emphasis on the epidemiology and control of major foliar diseases of barley and wheat in the Atlantic provinces.

Qualifications

Applicants must possess a Ph.D. or have a lesser degree with research experience and productivity equivalent to a doctorate, in plant pathology. It is also essential, for applicants to receive further consideration, that they have experience in conducting research related to cereal pathology. Knowledge of English is essential.

How to Apply

Send your application form and/or résumé to:

D.E. Fraser

Public Service Commission of Canada

National Capital Region Staffing Office

Ottawa, Ontario K1A 0M7

Closing Date: April 30, 1979

Please quote the applicable reference number at all times.

UNIVERSITY OF OXFORD

SIBTHORPIAN PROFESSORSHIP OF RURAL ECONOMY

The electors intend to proceed to a selection to the Sibthorpian Professorship of Rural Economy which will fall vacant on September 1, 1979. On appointment the professor will be required to assume the duties of Head of the Department of Agricultural Science and subsequently, for a period of five years, of the Departments of Agricultural and Forest Sciences which are to be amalgamated. Thereafter the Iebdomadal Council will assign the leadership of the amalgamated departments to either the Sibthorpian Professor of Rural Economy or the Professor of Forest Science for specified periods of not less than five years at a time; the professor who for the time being is not head of department will act as deputy head.

The stipend of the professor is at present £10,828 a year plus pensionable allowance as head or deputy head of department.

Applications (nine copies) naming three referees but without testimonials, should be received not later than May 8, 1979 by the Registrar, University Offices, Wellington Square, Oxford OX1 2JD, from whom further particulars may be obtained. 46(A)

MEDICAL RESEARCH COUNCIL RESEARCH ASSISTANT (Technician/Research Officer Salary scale £3,261 to £4,902)

The M.R.C. Clinical Psychiatry Unit requires a Psychologist or Social Science Graduate, with some training in Statistics, to join a small team working on clinical and epidemiological studies of psychiatric illness. The applicant will be expected to assist with the analysis and interpretation of data derived from clinical studies and a psychiatric case register; familiarity with or an interest in the use of an advanced desk top calculator would be an advantage. The main interests of the Unit are suicide and attempted suicide, depression and the neurophysiology of mental illness.

The person appointed will receive training in research methods and be encouraged to develop an individual interest in specific aspects of the work. Salary will depend on experience. The post becomes vacant on June 1, 1979, and is for the duration of 3 years.

Applications to the Director, M.R.C. Clinical Psychiatry Unit, Graylingwell Hospital, Chichester, Sussex PO19 4PQ, enclosing curriculum vitae and the names of two referees. Closing date for applications: April 20, 77(A)

COMMONWEALTH AGRICULTURAL BUREAUX Vacancy for SCIENTIFIC INFORMATION OFFICER

at the
COMMONWEALTH
FORESTRY BUREAU

Commonwealth Forestry Institute, South Parks Road, Oxford OX1 3RD
Duties of post: The scrutiny of technical literature, selection and preparation of abstracts in many subjects related to forestry or forest products (this may involve visits to outside libraries), indexing, preparing for the press and dealing with technical enquiries.

Flexible working hours are based on 37 hours per week. Applicants wishing to work 18½ hours per week, with appropriate adjustments of salary, etc., will be considered.

Qualifications: Applicants should be graduates in forestry or in a biological science or in a relevant branch of physical or engineering science. Strong preference will be given to candidates with a good reading knowledge of Russian.

Salary: In the range £2,998 to £5,448 per annum and a compensatory allowance (taxable but not superannuable) of 3.3 per cent to offset personal contribution to Superannuation. Starting salary according to qualifications, experience and age. Promotion to higher scales on merit.

Application forms and full particulars from:

The Executive Director,
Commonwealth Agricultural
Bureaux,

Farnham House, Farnham Royal,
Slough SL2 3BN.

Closing date for applications: April 30, 1979. 33(A)

LINCOLN COLLEGE (University College of Agriculture)

New Zealand

ASSISTANT LECTURER/ LECTURER IN SOIL SCIENCE

(DEPARTMENT OF
SOIL SCIENCE)

The Council of Lincoln College invites applications for appointment to a Lectureship in Soil Science. Applications will be considered from graduates in Agricultural Science or in any other discipline covering the general field of soil-plant relations, but preferably with a sound background in Chemistry.

The successful applicant will be appointed either as an Assistant Lecturer or Lecturer at a salary commensurate with his qualifications and experience. Current academic scales are: Assistant Lecturer NZ\$8,682 to NZ\$10,659; Lecturer NZ\$11,894 to NZ\$14,615. New Zealand Government Superannuation is available. Removal and travel expenses reimbursed up to specified limits.

Further details and Conditions of Appointment are obtainable from the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the College.

Applications close on April 30, 1979. 41(A)

UNIVERSITY OF GLASGOW INSTITUTE OF NEUROLOGICAL SCIENCES

RESEARCH FELLOW (IMMUNOLOGY)

Work involves study of senile dementia and other diseases of the brain. Previous experience of cell culture and immunofluorescence techniques desirable.

Salary in scale £4,000 to £6,000 according to experience and qualifications.

Apply with curriculum vitae to:

Dr P. O. Behan,

Senior University Lecturer in

Neurology,

Institute of Neurological Sciences,

Southern General Hospital,

Glasgow G51 4TF. 90(A)

UNIVERSITY OF MALAYA

Applications are invited for the following CHAIRS in the University of Malaya.

Faculty of Dentistry:

CHAIR OF CHILDREN'S DENTISTRY

Candidates should have high academic qualifications and wide experience in teaching and research. They are also required to undertake research and to have publications of academic standing.

Faculty of Science:

CHAIR OF INORGANIC CHEMISTRY

CHAIR OF PHILOSOPHY OF SCIENCE

Candidates should possess the following: (1) Ph.D. in the required field with—(a) 3 years experience as Senior Lecturer/Reader/Associate Professor; or (b) 5 years experience as Lecturer; or (2) A Master's degree in the required field with—(a) 5 years experience as Senior Lecturer/Reader/Associate Professor; or (b) 8 years experience as Lecturer. Candidates are also required to undertake research and to have publications of academic standing.

Salary Scales (All inclusive) [approx. sig. equiv.]: £8,313 by 420 to £8,733/ Review Point £9,014 by 420 to £9,434.

Further particulars and application forms are obtainable from the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF.

The closing date for the receipt of applications is April 15, 1979. 60(A)

FACULTY POSITION IN NATURAL PRODUCTS CHEMISTRY

DEPARTMENT OF
ENTOMOLOGICAL SCIENCES,
COLLEGE OF NATURAL

RESOURCES
UNIVERSITY OF

CALIFORNIA, BERKELEY

Full-time, 11-month research (80%) and teaching (20%) position available in Natural Products Chemistry at the Assistant Professor level. Ph.D. in organic chemistry or other field(s) relevant to natural products required with evidence of interest in chemicals active in insects.

Responsibilities will be in basic and applied research involving bioactive chemicals from insects, plants, and other biological materials that influence insect growth, development, reproduction, and behaviour. Research will include identification and synthesis of active components, and studies on their potential use in managing insect populations. Teaching duties may include developing a course in chemical ecology, environmental chemistry, insect biochemistry, or chemical pest control.

Send full curriculum vitae, official transcripts, copies of significant publications or manuscripts, and names of at least three references by April 1, 1979 to Evert I. Schlinger, Acting Chairman, Department of Entomological Sciences, 137 Giannini Hall, University of California, Berkeley, California 94720. The University of California is an equal opportunity, affirmative action employer. 39(A)

UNIVERSITY OF ESSEX FELLOW IN THE

DEPARTMENT OF PHYSICS

Applications are invited for the SRC-supported post of Fellow (Range 1A) in the above department, tenable for three years starting as soon as possible (salary scale £3,883 to £6,555, under review). The person appointed will be engaged in experimental studies of wave-wave interactions in laser-generated plasmas and will participate generally in the work of the Laser Plasma Interaction Group at the SRC Rutherford Laboratory Laser Facility.

Applications (three copies), including a curriculum vitae and the names and addresses of two referees, should reach the Registrar (AG/70/N), University of Essex, Wivenhoe Park, Colchester CO4 3SQ, from whom further particulars may be obtained, by April 5, 1979. 4(A)

**FACULTY POSITION IN
INSECT PATHOLOGY
DEPARTMENT OF
ENTOMOLOGICAL SCIENCES
COLLEGE OF
NATURAL RESOURCES
UNIVERSITY OF
CALIFORNIA, BERKELEY**

Full-time, 11-month research (75%) and teaching (25%) position available in insect pathology at the Assistant Professor level available July 1, 1979. Expertise mandatory in one of the following areas: bacteriology, comparative virology, mycology, or protozoology. Ph.D. and background in pathology required and postdoctoral experience desirable.

Responsibilities will be in basic and applied research and teaching in insect pathology and pest management. Experience in pathogen-insect relationships, pathogenicity, and the manipulation of pathogens for insect control will be weighing factors when judging applicants.

Send full curriculum vitae, official transcripts, copies of significant publications or manuscripts, and names of three references by April 1, 1979, to Evert I. Schlinger, Acting Chairman, Department of Entomological Sciences, 137 Giannini Hall, University of California, Berkeley, California 94720. The University of California is an equal opportunity, affirmative action employer. 40(A)

**CHELSEA COLLEGE
University of London
BIOLOGICAL SCIENCES GROUP
LECTURESHIP IN
APPLIED MYCOLOGY**

Applications are invited for the vacant post of Lecturer in the Department of Applied Biology, Biological Sciences Group. Candidates should preferably hold a Ph.D. degree or equivalent and have had some postdoctoral research experience in the area of applied mycology and/or plant pathology. Additional interests in the chemical control of plant disease or the genetical aspects of plant pathogen control would be an advantage.

Salary scale: £3,883 to £7,754 per annum (under review) plus £450 London Allowance.

Application forms and further particulars may be obtained from the Personnel Officer, Chelsea College, Friese Greene House, Chelsea Manor Street, London SW3 3TW. Closing date: April 6, 1979. 91(A)

**MOLECULAR BIOLOGY OF
ONCOGENIC VIRUSES
ASSISTANT OR
ASSOCIATE MEMBER**

The Division of Virology, St Jude Children's Research Hospital, invites applications from individuals with promise (assistant) or evidence (associate) of outstanding research abilities. We favour candidates with interests in nuclear DNA viruses (papova, adeno, herpes) and experience in recombinant DNA technology. However, exceptional candidates with other research interests will be considered. This is a full-time research position with no teaching or service responsibilities. St Jude Hospital is an equal opportunity employer. Please submit curriculum vitae, summary of research plans, and names of three referees to: Dr Allan Granoff, Chairman, Division of Virology, St Jude Children's Research Hospital, Memphis, TN 38101. 92(A)

**BLOOD GROUP REFERENCE
LABORATORY
SCIENTIFIC OFFICER**

A graduate is required to assist Dr C. M. Giles in reference work related to blood transfusion. This laboratory is recognised by the World Health Organisation as a Collaborating Laboratory for Reference and Research in Blood Grouping and many varied problems are investigated. Opportunities are available for study for a higher degree. Experience in the field of blood transfusion desirable.

Applications in writing, with curriculum vitae to Miss K. Lomas, Blood Group Reference Laboratory, Gatliff Road, off Ebury Bridge Road, London SW1W 8QJ. 9972(A)

**Notice of Vacancy
DIRECTOR**

**University of Minnesota
ST PAUL CAMPUS LIBRARIES**

Under the general direction of the Director of University of Minnesota Libraries, the Director of the St Paul Campus Libraries is responsible for the administration of this Department, which includes a Central Library, which is undergoing major expansion, and six physically separate subject libraries. The collections total over 200,000 catalogued volumes as well as substantial holdings in government publications and other materials, which support programmes in agriculture, biological sciences, and veterinary medicine. There is an operating budget of \$770,000, including \$275,000 for acquisition and binding, and a staff of 41 FTE, including 12 professionals. As director of one of the seven major departments in the University Libraries, the individual participates fully in University Libraries-wide planning and programme development.

Applicants must have demonstrated exceptional skills in leadership, administration, planning, and interpersonal relations. They must possess the M.L.S. or an appropriate equivalent, as well as significant applicable experience in a major university library. An educational background in the agricultural, biological sciences, or supporting science is desirable. Applicants should be able to meet the requirements of a universities libraries faculty appointment with tenure at the rank of associate professor or professor.

The minimum starting salary is \$25,000; this includes an administrative stipend.

Closing date for receipt of applications: May 15, 1979.

The University of Minnesota is an equal opportunity educator and employer.

Send application and detailed resume and names of three references to: Clarence Carter, Personnel Officer, 499 Wilson Library, University of Minnesota, Minneapolis, Minnesota 55455. 93(A)

**UNIVERSITY OF
NEWCASTLE UPON TYNE
READERSHIP IN
PHYSIOLOGY**

Applications are invited for an appointment from September 1, 1979 to a vacancy in an established Readership in Physiology. The Department of Physiology is responsible for teaching and research in Physiology and Physiological Biochemistry.

Salary will be at a point according to age, qualifications and experience on either the pre-Clinical Reader's scale £8,508 to £9,263 (under review) for a medically qualified appointee or the non-medical Reader's scale £7,506 to £9,263 (under review) with membership of the appropriate University superannuation scheme.

It may be possible to negotiate a clinical sessional commitment of Consultant status for a medically qualified appointee in acknowledgement of defined clinical duties and responsibilities.

Further particulars may be obtained from the Deputy Registrar, University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne NE1 7RU, with whom applications (15 copies) giving the names of not more than three referees, must be lodged not later than April 14, 1979. (Applicants from outside the British Isles may submit one copy only). 82(A)

**Queen's University at Kingston
POSTDOCTORAL
APPOINTMENTS**

in Solid State Physics, Nuclear Physics and Astronomy.

Specific fields include:

- Stellar Structure and Evolution
- Fast Ion Transport in Solids
- Experimental Nuclear Physics
- Theoretical Nuclear Physics
- Positron Studies of Metals
- Low Temperature Studies
- Physics of Dielectrics

Salary: ca. \$13,000 with N.S.E.R.C. approval. Submit applications with three references to Dr M. Sayer, Head, Department of Physics, Queen's University, Kingston, Ontario, Canada K7L 3N6. 94(A)

Occupational Hygiene

in newly formed units at Devonport, Portsmouth, Rosyth and Chatham

The Occupational Health Organisation of the MOD (Navy) provides a comprehensive medical, nursing and hygiene service to HM naval bases and regional shore establishments in the UK. These posts, in the regional hygiene units, offer experienced and newly qualified hygienists the opportunity to develop and apply their specialist knowledge in an important and expanding field. Each Unit will be staffed by two officers working on the identification, measurement and evaluation of a variety of chemical and physical hazards and advising on suitable methods of control. This will involve close liaison with the safety organisation, MOD Laboratories, the Institute of Naval Medicine and regional establishments.

Candidates, normally aged under 32, should have a good honours degree or equivalent in an appropriate discipline. The Diploma of Occupational Hygiene, Membership of the Institute of Occupational Hygienists or equivalent is essential for some posts, which are at senior scientific officer level.

Appointment as Senior Scientific Officer (£5150-£6900), Higher Scientific Officer (£4100-£5450) or Scientific Officer (£2840-£4410) according to qualifications and experience. Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by 6 April 1979) write to Ministry of Defence, CM(S)rb3, Room 210, Savoy Hill House, Strand, London WC2E 0BX. Please quote ref: SA/2/E.

Ministry of Defence

Ministry of Agriculture, Fisheries and Food, Fisheries Laboratory, Burnham on Crouch

Protection of the Marine Environment

This post is in the Aquatic Protection Division of the Laboratory, where the scientist appointed will be responsible for advising on the effect of effluent discharges on the marine environment, particularly tidal and estuarine waters. This work will require the use of a variety of data sources related to land based discharges and petroleum hydrocarbons and calls for an ability to assess the significance and extent of pollutants in the marine and other aquatic environments.

Candidates, normally aged under 32, should have a good honours degree, or equivalent, in mathematics, physics, engineering, chemistry or closely related discipline, coupled with at least 4 years relevant experience. A knowledge of effluent control is highly desirable.

Appointment as Senior Scientific Officer (£5150-£6900) with starting salary according to qualifications and experience. Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by 6 April 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). Please quote ref: SB/44/AD.

**WELLCOME
REAGENTS
LIMITED**

Production Manager

Wellcome Reagents Limited, part of The Wellcome Foundation Limited, a major British-owned international pharmaceutical company, manufactures a wide range of *in vitro* diagnostic reagents covering Immunology, Bacteriology, Serology and Clinical Chemistry.

We currently seek a Production Manager who, reporting to the General Manager, will be responsible for all Reagents production and distribution operations located on our Beckenham and Hither Green sites, employing around 130 staff.

Candidates, men or women, with a degree or equivalent qualification in life sciences or laboratory medicine, should have at least 5 years' successful experience in the production of biologically based products. Good administrative skills are essential.

Salary will attract candidates currently earning around £9,000+. Excellent conditions of employment include pension scheme, 4 weeks' holiday and generous relocation expenses where appropriate.

Please write, giving brief relevant details of background and experience, to the Personnel Manager, The Wellcome Research Laboratories, Langley Court, Beckenham, Kent BR3 3BS.

THE OPEN UNIVERSITY FACULTY OF SCIENCE

Assistant Cartographer (EARTH SCIENCES)

The successful applicant would be expected to prepare geological maps and diagrams for research publications, undergraduate courses, displays, meetings and symposia.

Applicants should have four years' practical cartographic experience, period of training inclusive. A recognised cartographic qualification would be desirable but proven ability to produce high quality artwork for reproduction (black and white and colour) is essential and short-listed candidates would be expected to present a portfolio of their work at interview.

Salary on the scale £2,955 to £3,402 p.a. (under review)

Ref: 3791

Research Technician (BIOLOGY)

Dr Richard Holmes requires a technician to assist his Research Group investigating Biochemical and Physiological variations in fish and amphibians. The post would suit someone able to work on their own initiative and wishing to be actively involved in an expanding research project.

Applicants should possess an H.N.C. or equivalent and at least six years' experience in Biochemical or Biology Research.

Salary on the scale £3,186 to £3,720 p.a. (under review).

Ref: 1983

Application forms and further particulars are available from the Recruitment Office (JD3780/3), The Open University, P.O. Box 75, Walton Hall, Milton Keynes MK7 6AL or telephone Milton Keynes 63404: there is a 24 hour answering service on 63868.

PLEASE QUOTE THE REFERENCE NUMBER OF THE POST IN WHICH YOU ARE INTERESTED.

Closing date for applications: March 29

UNIVERSITY OF NEWCASTLE New South Wales FACULTY OF MEDICINE SENIOR LECTURESHIPS IN PATHOLOGY (3) ANATOMICAL PATHOLOGY MICROBIOLOGY IMMUNOLOGY

The Faculty of Medicine is developing a fully integrated curriculum, based on clinical problem-solving in small groups, within a non-departmental organisational structure. Research interests currently represented in the area of Pathology include mucosal immunology and host defences, molecular, cellular and epidemiological studies of virus infections, tissue localisation of antigens. The appointees will be expected to contribute to the teaching programme and to develop research relevant to their own interests; they will be encouraged to participate in laboratory and/or clinical aspects of their specialty in the teaching hospitals of the Hunter region (e.g. as an anatomical pathologist, infectious diseases physician or clinical immunologist). A medical qualification is desirable but not essential.

Commencing salary is within the range \$A21,180 to \$A24,667 per annum depending upon qualifications and experience. A clinical loading of up to \$A5,000 per annum depending on the degree of clinical responsibility may be paid to medically qualified appointees. There is a limited right of private practice.

For further information regarding academic matters and teaching duties contact Professor R. Clancy at the Royal Newcastle Hospital, New South Wales.

Applications close May 4, 1979. GENERAL INFORMATION: Conditions of employment including method of application and other particulars may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PP.

72(A)

THE AUSTRALIAN NATIONAL UNIVERSITY RESEARCH SCHOOL OF PHYSICAL SCIENCES DEPARTMENT OF THEORETICAL PHYSICS POSTDOCTORAL FELLOW/ RESEARCH FELLOW/ SENIOR RESEARCH FELLOW

Applications are invited for appointment as Postdoctoral Fellow, Research Fellow or Senior Research Fellow in the Department of Theoretical Physics, Research School of Physical Sciences (one appointment). The Department would prefer to make an appointment in the research areas of elementary particle physics or field theory, but applications from theoretical physicists with research interests in other areas will be considered. The Department's main current interests are in fundamental aspects of particles and fields, statistical mechanics, solid-state physics, plasma physics and nuclear physics. A substantial part of the work is related to the experimental interests of the Research School.

CLOSING DATE: MAY 18, 1979.

SALARIES will be in accordance with qualifications and experience within the range: Postdoctoral Fellow, a fixed point between \$A15,786 and \$A20,606 per annum; Research Fellow \$A15,786 to \$A20,606 per annum; Senior Research Fellow \$A22,049 to \$A26,301 per annum. Current exchange rates: \$A1=56p, \$US1.13.

TERMS OF APPOINTMENT: Postdoctoral Fellow—between one year and two years; Research Fellow/Senior Research Fellow—three years in the first instance with the possibility of extension to five years.

OTHER CONDITIONS: Reasonable appointment expenses are paid. Superannuation benefits are available for applicants who are eligible to contribute. Assistance with housing is provided for an appointee from outside Canberra.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should obtain the further particulars from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PP. 73(A).

UNIVERSITY OF LEICESTER DEPARTMENT OF PHYSICS RESEARCH ASSOCIATE IN CONDENSED MATTER PHYSICS

Applications are invited for a postdoctoral research associate to undertake a study of liquid semiconducting alloys using photoelectron spectroscopy. The project is part of a wider investigation of the properties of disordered systems being carried out in the Physics Department and supported by the Science Research Council.

The post is tenable initially until September 1981 and the salary is from £3,843 per annum. Applications with a curriculum vitae and the names of two referees should be sent to Dr C. Norris, Department of Physics, University of Leicester, LE1 7RH. 9999(A).

FRESHWATER BIOLOGICAL ASSOCIATION WINDERMERE LABORATORY RESEARCH ASSISTANT

Applications are invited for the post of research assistant to work on the physiology of teleost fish. Experience with chromatography, radio isotopic techniques and electron microscopy useful but not essential.

The salary scale, according to age, qualifications and experience, will be either £2,188 to £3,303 (Assistant Scientific Officer) or £2,839 to £4,415 (Scientific Officer). Persons expecting to graduate in July 1979 may be considered for this post.

Further details and application forms from: The Secretary, Freshwater Biological Association, The Ferry House, Ambleside, Cumbria LA22 0LP. 31(A).

**AGRICULTURAL
RESEARCH COUNCIL
INSTITUTE OF
ANIMAL PHYSIOLOGY
BABRAHAM
CAMBRIDGE CB2 4AT
Neurobiological Research**

As part of an expanded programme of work in Neurobiology at Babraham the following three new research appointments are available at Senior Scientific Officer level.

N.B.1. Peptide chemist for research in Neuroendocrine Group on peptidergic neurones. Candidates should have experience in isolation and characterisation of neuropeptides and an interest in collaboration with neurophysiologists.

N.B.2. Behavioural physiologist to investigate brain mechanisms in motivational behaviour of farm animals.

N.B.3. Neurophysiologist for research involving single unit neuronal recording from conscious animals to study neural mechanisms in ingestive behaviour of farm animals.

Candidates should possess a first or upper second class honours degree together with at least four years relevant postgraduate experience, with preferably a Ph.D. degree and a good record of published work.

Salary £5,154 to £6,856 p.a. Non-contributory pension scheme.

Application forms and further details may be obtained from the Secretary of the Institute by quoting the appropriate reference number. Closing date for applications: April 2, 1979.

**PUBLIC HEALTH
LABORATORY SERVICE
BOARD
MICROBIOLOGIST
—BASIC GRADE**

Graduate Electron Microscopist

Applications are invited for the post of electron microscopist in the Public Health Laboratory and Department of Microbiology, Central Middlesex Hospital, London NW10. This post offers opportunities to develop electron-microscopy diagnostic techniques in clinical virology and other aspects of microbiology. In addition to a service commitment, the person appointed will be expected to undertake research work and to teach electronmicroscopy to members of the laboratory staff and others as required. Participation in other aspects of virology may be required on occasion. Applicants should possess a first-class (or upper second class) honours degree or higher qualification in microbiology.

N.H.S. terms and conditions of service. Salary scale £2,991 to £4,899 plus £354 London Weighting.

Closing date, April 5, 1979.

The laboratory may be visited by arrangement with the Director, Dr D. A. McSwiggan, 01-965 1603, to whom an application (giving curriculum vitae together with the names and addresses of three referees) should be sent.

64(A)

**INSTITUTE OF
BASIC MEDICAL SCIENCES
(University of London
and
Royal College of Surgeons
of England)**

**DEPARTMENT OF
PHARMACOLOGY**

Applications are invited from medical or science graduates for the post of

LECTURER

in the Department of Pharmacology. Candidates will be expected to have completed several years of postgraduate research in a subject related to the main research work of the department.

Salary scale £3,883 to £7,754 p.a., plus £450 London Allowance. (Award pending.)

Applications naming two referees to: Mr W. F. Davis, Secretary, Institute of Basic Medical Sciences, Royal College of Surgeons of England, Lincoln's Inn Fields, London WC2A 3PN, by Friday, April 20, 1979, from whom further particulars may be obtained.

67(A)

**KUWAIT
UNIVERSITY OF KUWAIT
FACULTY OF MEDICINE**

Medical Science and Clinical Appointments

Applications are invited for the following appointments in the Faculty of Medicine.

ANATOMY—Associate Professor. Candidates should have areas of specialisation in electron microscopy. The successful applicant responsibilities will include directorship of the E.M. Unit, which is equipped with scanning and transmission microscopes. Assistant or Associate Professor. Preference will be given to candidates who have experience of teaching the anatomical discipline to allied health students. The successful candidate will be responsible for co-ordinating allied health teaching in the Department of Anatomy.

COMMUNITY MEDICINE—Professor or Associate Professor in Epidemiology. Professor or Associate Professor in Public Health.

MEDICINE—Associate Professor. Candidates should be general physicians with a special interest in renal medicine and experience in haemodialysis, peritoneal dialysis and renal transplantation. Experience of renal morphology by light microscope would be an advantage.

MICROBIOLOGY—Professor or Associate Professor in Medical Bacteriology. Professor or Associate Professor in Clinical Bacteriology.

PATHOLOGY—Associate and Assistant Professors. Candidates should have experience in academic pathology, particularly in anatomic and histopathology. The successful candidates will have responsibilities in diagnostic pathology at the teaching hospitals.

PHYSIOLOGY—Professor or Associate Professor in Neurophysiology. Professor or Associate Professor in Endocrinology.

Professor or Associate Professor with specialisation in one of the following areas: Haematology, Gastrointestinal, Muscle & Cardiovascular.

SURGERY—Professor or Associate Professor in Urological Surgery. Associate Professor in Traumatology and Burns.

Assistant Professor in Orthopaedics. Applicants should possess a Ph.D. or equivalent higher medical qualification, and have conducted and published research in the field. Professors should have 14 years' experience, 4 as an associate professor or its equivalent, i.e. senior lecturer or reader. Associate professors should have 9 years' experience, 4 as an assistant professor or its equivalent, i.e. lecturer.

CONDITIONS OF APPOINTMENT

Salaries: Total monthly salaries will be within the following scales according to qualifications and experience (1KD=£1.80, US\$3 approx.).

Professors with clinical appointments: KD 755-860 (6 increments).

Professors medically or non-medically qualified with medical science appointments: KD 701-797 (6 increments).

Associate Professors with clinical appointments: KD 650-755 (6 increments).

Associate Professors medically qualified with medical science appointments: KD 605-701 (6 increments).

Associate Professors non-medically qualified: KD 575-665 (6 increments).

Assistant Professors with clinical appointments: KD 520-625 (6 increments).

Assistant Professors medically qualified with medical science appointments: KD 484-560 (6 increments).

Assistant Professors non-medically qualified: KD 460-550 (6 increments).

Clinical supplements: In addition to the above university salaries there will be a monthly clinical supplement paid by the Ministry of Public Health for medical school staff with clinical service commitments. These will be within the following scales:

Professor and Chairman: KD 200-250 (5 increments).

Professor: KD 150-200 (5 increments).

Associate Professor: KD 100-150 (5 increments).

Assistant Professor: KD 75.

Gratuity: There is a gratuity of one month's basic salary for each year employed which is payable on termination of contract.

Housing: Suitably furnished, air-conditioned accommodation, electricity and water are provided free of charge.

Medical Care: Free, comprehensive treatment is available in Kuwait under the State Health Service.

Travel: Airline tickets are provided from the country of recruitment for the appointee, spouse and up to 3 dependent children under 20 years. Thereafter return tickets are issued annually to the country of origin. On termination of contract, tickets are provided to the country of recruitment. A baggage and freight allowance is also provided. In addition, travel expenses for attending one scientific meeting a year are paid by the University.

Vacation: Sixty days paid annual leave as well as various official holidays.

Education: This is provided free in state schools where the instruction is in Arabic. Staff who have to send their children to non-Arabic schools in Kuwait will have the cost of up to a maximum of three met by the University.

Taxation: There is no income tax in Kuwait. Currency is freely transferable without restrictions.

Further details about these appointments and the method of application can be obtained from: The Dean, Faculty of Medicine, University of Kuwait, P.O. Box 5969, Kuwait.

Completed applications must be received by no later than April 25, 1979.

9993(A)

**UNIVERSITY OF GLASGOW
DEPARTMENT OF ZOOLOGY
RESEARCH ASSISTANT**

Applications are invited from graduates with a training in neurobiology to work on a project concerned with the function of interneurons in the connectives of the locust. The project is funded by the SRC and is supervised by Dr M. D. Burns.

The position will be for three years, with starting salary within £3,384 to £3,883 (Range 1B, Research and Analogous Staff Scales). It may be possible to register for a higher degree.

Applications, enclosing curriculum vitae and the names of two referees, should be sent to:

Dr M. D. Burns,
Zoology Department,
Glasgow University,
Glasgow G12 8QQ.

In reply please quote Ref No 4392M

**THE NATIONAL INSTITUTE FOR HIGHER
EDUCATION, LIMERICK, IRELAND**

Further expansion of the Institute is taking place at undergraduate and postgraduate levels within the extensive complex of world bank financed facilities which have been commissioned as part of the first phase of development of the riverside campus.

APPLIED MATHEMATICS-BUSINESS

Lecturer/Assistant Lecturer

Applicants should have particular expertise in the application of Mathematics to the solution of business problems.

APPLIED MATHEMATICS-CONTROL

Lecturer/Assistant Lecturer

Applicants should have particular expertise in the mathematical theory of control.

Applicants for the above posts should have experience in the application of Mathematics and should hold an appropriate Postgraduate qualification.

SALARY: Lecturer £6,901 to £8,766

Assistant Lecturer £5,294 to £6,592

Application material available from the Personnel Office, The National Institute for Higher Education, Limerick, Ireland, to be completed and returned by Friday, April 20, 1979.

80(A)

SENIOR ENGINEER

Signal Analysis
& Pattern Recognition

Newcastle-upon-Tyne up to £6,774

The British Gas On Line Inspection Centre has achieved an international reputation for the development of improved methods for inspecting high pressure pipelines. This has involved making use of advanced technology in several fields, namely electronics, computing and mechanical engineering. Due to rapid expansion, the Centre is moving to Cramlington, Northumberland, but is currently at Killingworth, Newcastle-upon-Tyne.

Computer analysis of the inspection data is a key aspect of the development programme. Signal analysis, pattern recognition and mathematical modelling expertise is required to develop and refine data processing techniques.

Applicants should be numerate graduates with a proven record of success in the above field. Previous experience with multi-sensor systems in seismology, medical inspection, speech recognition, ultrasonics or electromagnetics would be a distinct advantage as would a higher degree in a relevant subject. Extensive computing facilities are available.

Salary within the range £5,253 to £6,774 plus current self-financing productivity payment.

Excellent conditions of service are offered—these include pension and sick pay schemes.

Please write for an application form quoting reference OLI/331/N to Margaret Harrison, Personnel Assistant, On Line Inspection, Engineering Research Station, Killingworth, Newcastle-upon-Tyne.

Tel: (0632) 684828, ext. 380.

BRITISH GAS

98(A)

Scottish Institute of Agricultural Engineering

Head of Soils Section

Senior Scientific Officer/ Principal Scientific Officer

(Ref. AG/18/B)

Re-advertisement

Applications are invited for the post of Senior Scientific Officer/Principal Scientific Officer to lead a team investigating the effects of agricultural machinery on the physical properties of field soils with particular reference to cultivations, zero-tillage and compaction.

Qualifications

A first or upper second class honours degree, and preferably a higher degree, or equivalent qualifications in a relevant branch of science or engineering. The applicant should have had considerable experience of research in soil physics or soil mechanics.

Salary Scales

Appointment in the grade of Senior Scientific Officer (£5,154–£6,898) or Principal Scientific Officer (£6,609–£8,461) according to qualifications and experience. Non-contributory superannuation.

Application forms and further information from the Secretary, Scottish Institute of Agricultural Engineering, Bush Estate, Penicuik, Midlothian, EH26 0PH, to whom applications should be submitted by April 2, 1979. 9917(A)

POSITION DESCRIPTION PROFESSOR OF BIOCHEMICAL PHARMACOLOGY AND CHAIRPERSON DEPARTMENT OF PHYSIOLOGY, BIOCHEMISTRY AND PHARMACOLOGY

The New York State College of Veterinary Medicine at Cornell University invites nominations and applications for the position of Chairperson of the Department of Physiology, Biochemistry and Pharmacology. The speciality of the applicant should be within the discipline of biochemical pharmacology. Credentials should include evidence of outstanding research achievements and potential, administrative ability and considerable teaching experience, and there should be a demonstrated commitment to excellence in teaching and research.

The department is multidisciplinary with responsibility for teaching, research and service. The 17,000 square feet of teaching and research laboratory space and 6,000 square feet of specialised animal-holding space are well-equipped for research and instruction on a wide range of subjects and species. The department is also engaged in interdisciplinary research projects and training programs in toxicology and comparative gastroenterology.

Applicants should submit their curriculum vitae, and request that three letters of recommendation be sent directly to the Search Committee. Applications accepted through June 1, 1979.

Please address all correspondence to: Professor R.H. Wasserman, Chairman Search Committee, Department of Physical Biology, New York State College of Veterinary Medicine, Cornell University, Ithaca, New York 14853.

Affirmative Action/Equal Opportunity Employer. 30(A)

FACULTY POSITION AVAILABLE IN RETINAL HEMODYNAMICS AND BLOOD FLOW STUDIES

University of Illinois

Eye and Ear Infirmary

and
Abraham Lincoln School
of Medicine

The University of Illinois
at the

Medical Center, Chicago

Equal Opportunity/Affirmative
Action Employer

Applications are invited for a faculty position at the assistant or associate professor level. The major responsibility will be supervision of research of vascular flow in the retina, utilizing a unique non-invasive computerised ophthalmoscopy system. Active interchange with engineers and clinical ophthalmologists will be fostered. An advanced degree (Ph.D. or M.D.) is a prerequisite.

Those interested should direct inquiries together with a curriculum vitae and bibliography to

Morton F. Goldberg, M.D.
Professor and Head
Department of Ophthalmology
University of Illinois Eye and
Ear Infirmary
1855 West Taylor Street
Chicago, Illinois 60612
312 996-6590. 95(A)

LABORATORY SCIENTIFIC OFFICER with HNC or equivalent qualification (or Junior Laboratory Scientific Officer of high quality) required as soon as possible for one year to complete an M.R.C. supported study on cytomegalovirus infections in Department of Microbiology. Experience in virology or cell culture essential. Salary for qualified Laboratory Scientific Officer not less than £3,261 plus £354 London Weighting. Applications with full details and names of two referees to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. M.C. 10(A)

UMIST DEPARTMENT OF MATHEMATICS LECTURER IN MATHEMATICS (OPERATIONAL RESEARCH)

Applications are invited from candidates of either sex for the above post. Applicants may have research interests in any branch of Operational Research (stochastic and/or deterministic).

Salary will be in the range £3,883 to £7,754 (under review) and the appointee will be expected to commence duties by September 1 or as soon as possible thereafter by arrangement.

Write for application forms and further particulars quoting reference MAT/34/A1 to the Registrar UMIST, P.O. Box 88, Manchester M60 1QD. 70(A)

WELSH NATIONAL SCHOOL OF MEDICINE DEPARTMENT OF MEDICINE and UNIVERSITY COLLEGE, CARDIFF

DEPARTMENT OF
BIOCHEMISTRY

TWO POSTDOCTORAL RESEARCH OFFICERS

Applications are invited for two Research Officer positions, one work with Dr John Kay at University College, Cardiff, and the other with Dr R. Marks, Reader and Consultant in Dermatology, Welsh National School of Medicine, on a collaborative project to identify serum component of possible importance in wound healing. The work in the first post will include large scale fractionation of human serum while the second will be involved with assay systems, org culture and histometric techniques.

Candidates for the first post should have, or expect to obtain shortly, a Ph.D. degree in Biochemistry or a related subject and research experience in protein purification systems, especially affinity chromatography and ultrafiltration procedures would be an advantage. For the second post, a Ph.D. in Biochemistry or other biological discipline would be acceptable and experience with histologic procedures and tissue culture system would be advantageous.

The appointments, which will be for one year in the first instance (renewable for a second year) are financed by a grant from the Medical Research Council. Starting salaries up to £3,800 per annum (under review).

Applications in the form of a curriculum vitae, with the names and addresses of two referees, should be sent to the Registrar and Secretary, Welsh National School of Medicine, Health Park, Cardiff, 3 weeks from the date of appearance of this advertisement (quoting Ref No M6/53). 65(A)

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR DEMONSTRATOR IN MARINE BIOLOGY

Applications are invited for the above appointment, to commence as soon as possible.

The successful applicant will be required to assist the preparation of teaching of practical classes, the courses and tutorial classes in marine zoology, particularly in its ecological aspects. Facilities for individual research will be available.

The appointment will be to the Oth Related IB Scale £3,384 to £5,604 p annum, and will be for one year in the first instance.

Applications (two copies), giving details of age, education and experience, together with the names and addresses of two referees, should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DX. Closing date for applications: March 26, 1979. 83(A)

UNIVERSITY OF LONDON CHAIR OF CLINICAL IMMUNOLOGY AT THE CARDIOTHORACIC INSTITUTE

The Senate invites applications for the above Chair.

The Cardiothoracic Institute is associated with the Brompton, the National Heart and London Chest Hospitals, but the holder of the Chair will head the Department of Clinical Immunology at the Fulham Road Branch, linked to the Brompton Hospital. Within the Institute there is a number of other units with complementary interests, including pharmacology, microbiology, pathology, oncology and occupational lung disease, as well as adult and paediatric clinical departments with whom collaboration would be encouraged. Appropriate clinical facilities are available at the Brompton Hospital and the opportunity exists to develop further links with the other Hospitals within the Group.

Applications (11 copies) must be received not later than April 27, 1979 by the Academic Registrar (N), University of London, Malet Street, London WC1E 7HU, from whom further particulars and the salary scale should first be obtained. 42(A)

THE HANNAH RESEARCH INSTITUTE FOR STUDIES RELATING TO THE PRODUCTION AND UTILISATION OF MILK METABOLIC PHYSIOLOGIST

A vacancy exists for a Higher Scientific Officer in the Physiology Department to study metabolism in goats and cows in relation to the control of milk secretion and to nutritional and environmental factors.

Applicants should possess a First or Upper Second Class Honours Degree in a relevant discipline with, preferably, a Ph.D.

Salary will be in the range £4,101 to £5,448. At least two years' relevant postgraduate experience is required for appointment to HSO. Non-contributory pension scheme in operation.

Further particulars may be obtained from:

**The Secretary
The Hannah Research Institute
AYR KA6 5HL**

to whom applications, which should include a curriculum vitae, list of publications, and the names and addresses of three referees, should be sent by: April 12, 1979. 87(A)

WESTMINSTER MEDICAL SCHOOL RESEARCH ASSISTANT

Organic Chemist or Biochemist, required to join a small team working on pigment changes in disease. Work will include the isolation and assay of pigment intermediates from the body fluids of patients undergoing treatment. Post available for 1 year, initially.

Salary on the Whitley Council Scale for Hospital Biochemists.

Applications, with curriculum vitae and the names of two referees, to Professor J. R. Hobbs, Department of Chemical Pathology, Westminster Medical School, 17 Page Street, London SW1P 2AR, by March 30, 1979. 79(A)

RESEARCH CHEMIST

A Research Chemist to work in the areas of co-ordination and bio-inorganic chemistry is required for research, in the first instance, into the chemistry of molybdenum iron-sulphur cluster systems and related species.

The post is in the Higher Scientific Officer grade, on a salary scale increasing from £4,101 to £5,448 per annum, by eight yearly increments.

Qualifications: 1st or upper 2nd class honours degree with at least two years relevant postgraduate experience.

Superannuation under a non-contributory scheme.

Applications in writing to the Secretary, Agricultural Research Council, Unit of Nitrogen Fixation, University of Sussex, Brighton, Sussex BN1 9RQ, with curriculum vitae and the names of three referees. Closing date: March 30, 1979. 74(A)

SENIOR/ASSOCIATE SCIENTISTS IN EXPERIMENTAL CELL MORPHOLOGY AND CYTOGENETICS

The W. Alton Jones Cell Science Center is interested in expanding its research program by the recruitment of two new staff members at the level of SENIOR or ASSOCIATE SCIENTIST (FULL OR ASSOCIATE PROFESSOR EQUIVALENT). The Center is an operational unit of the Tissue Culture Association and has an active program of research on a variety of topics. It is concerned, as well, with advanced training and education involving cell tissue and organ cultures. The laboratories are modern, spacious, and well equipped. The Center has affiliations with the University of Vermont, SUNY at Plattsburgh, and the University of Rhode Island.

Suitable candidates will have a Ph.D. or M.D. and have made significant contributions to their chosen field. They should currently hold positions of not less than Assistant Professor or equivalent. It is expected that the candidates' research will involve the use of cell tissue or organ culture. It is expected as well that the candidates will have an established track record in obtaining research support from the funding agencies.

For further information on the Center and its programs, contact the Office of the Director, W. Alton Jones Cell Science Center. Resumes and names of four references to the Chairperson, Search Committee, In Care of W. Alton Jones Cell Science Center, Old Barn Road, Lake Placid, New York 12946.

The W. Alton Jones Cell Science Center is an Affirmative Action/Equal Opportunity Employer. Applications from women and minority groups are encouraged. 9922(A)

AGRICULTURAL RESEARCH COUNCIL INSTITUTE OF ANIMAL PHYSIOLOGY, BABRAHAM, CAMBRIDGE CB2 4AT

A vacancy exists in the Immunology Department for a research scientist who has made a significant contribution to the field of cellular physiology of the immune response. The candidate should be experienced in the analysis of lymphocyte and macrophage kinetics *in vivo*, with particular reference to cells engaged in the immune response, and in the induction and maintenance of tolerance. Applicants should have a first or upper second class honours degree and preferably a Ph.D. in a relevant subject. Appointment as Principal Scientific Officer—£6,609 to £8,461 p.a. Non-contributory superannuation scheme. Applications should be sent to the Secretary of the Institute by April 2, 1979, quoting Ref. I.D.4. 35(A)

UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENT OF ZOOLOGY The University invites applications for the post of DEMONSTRATOR

in the Department of Zoology. Preference will be given to candidates with experience in comparative physiology or experimental zoology. Applicants should possess a higher degree or have equivalent postgraduate research experience. The appointment will be for a period of three years tenable from September 1, 1979.

Salary will be at an appropriate point on the Grade IB (bar) scale £3,884 to £4,882 per annum according to age, qualifications and experience. Membership of the appropriate university superannuation scheme will be required.

Further particulars may be obtained from the Senior Assistant Registrar, The University, 6 Kensington Terrace, Newcastle upon Tyne NE1 7RU, with whom applications (three copies), together with the names and addresses of three referees, should be lodged not later than April 9, 1979. Please quote reference N. 20(A)

Plant Virologist

Senior Scientific Officer/ Higher Scientific Officer/ Scientific Officer

£2,839 to £6,898

Applications are invited for a pensionable post in the Plant Pathology Division of the Department of Agriculture.

The successful candidate will be expected to conduct research and provide specialist advice on plant virus diseases with particular reference to diseases of grass, forage, cereal and horticultural crops.

The person appointed may also be required to undertake teaching duties in the Faculty of Agriculture and Food Science, Queens University, Belfast.

SENIOR SCIENTIFIC OFFICER

Over 25 and under 32 years of age on December 31, 1979 with a first or second class honours degree in a scientific or agricultural discipline pertinent to Plant Pathology with at least 4 years' postgraduate experience in Plant Virology.

HIGHER SCIENTIFIC OFFICER

Under 30 years of age on December 31, 1979 with an honours degree as above and at least 2 years' appropriate postgraduate experience.

SCIENTIFIC OFFICER

Under 27 years of age on December 31, 1979 with an honours degree as above. Exceptionally applications may be considered from candidates over the age limits who have specialised experience.

The Civil Service Commissioners may decide to interview only those applicants who appear from the information available (including the level of academic attainment and relevant experience) to be best qualified.

SALARY SCALES

Senior Scientific Officer	£5,154 to £6,898
Higher Scientific Officer	£4,101 to £5,448
Scientific Officer	£2,839 to £4,415

(The salary scale will be subject to review from April 1, 1979).

Grading and starting salary will be related to qualifications and experience. There are prospects of promotion to Principal Scientific Officer (£6,609 to £8,461).

Please write or telephone for an application form quoting job reference SB 137/79/T to the Civil Service Commission, Rosepark House, Upper Newtownards Road, Belfast BT4 3NR (telephone Dundonald 4585 ext 256). Completed forms must be returned to arrive not later than March 29, 1979. (27A)

NORTHERN IRELAND CIVIL SERVICE

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY DEPARTMENT OF BIOCHEMISTRY POSTDOCTORAL RESEARCH ASSISTANT

required to join a group involved in genetic manipulation of industrial microorganisms for new fermentation processes. Experience in some aspects of recombinant DNA technology would be an advantage. The appointment is available from October 1, 1979 and would be for two years in the first instance on the scale £3,883 to £6,555 plus London Allowance, £450 per annum.

Applications including a curriculum vitae together with an indication of relevant experience and future aspirations for research should be addressed to Professor B. S. Hartley, F.R.S., Department of Biochemistry, Imperial College, London SW7 2AZ. 44(A)

UNIVERSITY OF GLASGOW TEMPORARY LECTURESHIP IN GEOLOGY

Applications are invited for a temporary lectureship in the Department of Geology during the session 1979-80 in marine ecology and sedimentology. Research experience in palaeontology and interaction of organisms and sediments would be valuable.

Salary will be within the range £3,975 to £5,830 of the Lecturers' scale £3,975 to £8,250, with placement according to age, qualifications and experience.

Applications (8 copies), giving the names and addresses of three referees, should be received by the Secretary of the University Court (Room 18), University of Glasgow, Glasgow G12 8QQ by April 13, 1979. Further particulars may be obtained from Professor B. E. Leuke, Department of Geology (Tel 041-339 8855, ext. 7435).

In reply please quote Ref. No. 4393 97(A)

Firmenich

Leading international company engaged in the manufacture and supply to industry of synthetic perfumes and flavours has an opening for a

SENIOR TOXICOLOGIST

at its corporate headquarters in Geneva, Switzerland.

Reporting directly to the corporate Management, the person appointed will assume the following major responsibilities:

- to represent FIRMENICH worldwide in matters of product safety;
- to provide a comprehensive advisory service to customers and government agencies, as well as to other companies in Firmenich's international Group;
- and, in general, to help formulate and implement Group policy for product safety, including the organization, supervision and interpretation of toxicity and dermatology tests carried out by independent laboratories.

The successful candidate will already have made a substantial impact in this field.

Ability to speak and write fluently in English as well as a good working knowledge of French are necessary, other languages being a further asset.

For more information please write in confidence to

Mr. ERNEST K. WEBER, Director of Personnel

FIRMENICH SA - Département du Personnel
Case postale 239 - 1211 Genève 8

9925(A)

THE UNIVERSITY OF LANCASTER DEPARTMENT OF PHYSICS RESEARCH ASSOCIATE

Applications are invited for the post of postdoctoral Research Associate in the Low Temperature Physics group. The post is financed by S.R.C. for three years on the R.A. 1A scale (£3,883 to £6,555, under review). The research associate will work with Drs Pickett and Guénault on experiments below 1mK on superfluid helium-3. A nuclear demagnetisation refrigerator constructed for this research programme is now nearing completion.

Further particulars may be obtained (quoting reference L.123/D) from the Establishment Officer, University House, Bailrigg, Lancaster LA1 4YW, to whom applications (5 copies) naming two referees, should be sent not later than March 30, 1979. 96(A)

UMIST DEMONSTRATOR IN BIOCHEMISTRY

Applications are invited for a Demonstratorship, initially until September 30, 1980, but with the possibility of renewal. Duties include assistance with the teaching of undergraduates mostly in the laboratory and postgraduate research. Qualifications: recent Ph.D. or good degree in Biochemistry or related discipline. Laboratory experience in Microbial or Protein Biochemistry desirable but not essential. Salary up to £3,883 per annum.

Applications by letter, quoting reference BIO/35/AT, with curriculum vitae and the names of two referees should be addressed to Professor A. A. Eddy, Department of Biochemistry, UMIST, P.O. Box 88, Manchester M60 1QD. 69(A)

THE UNIVERSITY OF LEEDS DEPARTMENT OF EARTH SCIENCES Applications are invited for the post of LECTURER

in the Department of Earth Sciences. Duties will consist mainly of the teaching of structural geology at undergraduate level plus appropriate research according to the particular interests of the appointee.

Salary on the scale for lecturers: £3,883 to £7,754 per annum (under review), according to age, qualifications and experience.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 49/11/D. Closing date for applications: April 19, 1979.

Applicants from overseas may apply by telegram in the first instance, naming three referees. 11(A)

UNIVERSITY OF EDINBURGH FORBES CHAIR OF ORGANIC CHEMISTRY

Applications are invited for the Forbes Chair of Organic Chemistry which will become vacant on August 1, 1979, on the resignation of Professor J. I. G. Cadogan, F.R.S.

Further particulars may be obtained from the undersigned, with whom applications (12 copies) giving the names of three referees, should be lodged by May 9, 1979. Overseas candidates need submit only one copy of their application. Please quote Reference 3/79. 68(A)

THE UNIVERSITY OF LEEDS DEPARTMENT OF CHEMICAL PATHOLOGY Applications are invited for the post of LECTURER

in the above Department. Candidates should have a higher degree and some postdoctoral research experience.

An interest in planning, organising and taking major responsibility for the Neonatal, Paediatric and Obstetric aspects of the work of the Department would be an advantage. These activities will be sited in Phase I of the Leeds General Infirmary complex when this is opened in 1982. There will be excellent opportunities for research and the successful candidate will contribute to the teaching role of the Department.

Salary on the scale for lecturers: £3,883 to £7,754 (under review), according to age, qualifications and experience.

Those wishing to discuss the post in more detail or visit the Department should contact Professor D. B. Morgan (Telephone (0532) 32799, ext. 416).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 84/9/D. Closing date for applications: April 11, 1979. 71(A)

UNIVERSITE DE LAUSANNE

L'Université de Lausanne ouvre une inscription en vue de pourvoir le poste de

PROFESSEUR ORDINAIRE DE BIOLOGIE VEGETALE

enseignement: cours et travaux pratiques à des étudiants de 1er cycle (1ère année) et de 2e cycle (4e année)

orientation des recherches: contrôle biochimique et biophysique de la croissance des cellules végétales, avec préférence pour des problèmes de phytoenzymologie.

entrée en fonction: 1er septembre 1979.

Les candidatures (curriculum, plan de recherches et publications) doivent parvenir avant le 20 avril 1979 à M. le Doyen de la Faculté des Sciences, Collège propédeutique, 1015 Lausanne-Suisse. 84(A)

UNIVERSITY OF EDINBURGH DEPARTMENT OF ZOOLOGY LECTURER

(Sub-Department of Parasitology). Applications are invited for the post of Lecturer in the Department of Zoology (Sub-Department of Parasitology). Candidates must be prepared to teach helminthology.

Salary scale £3,883 to £7,754 per annum (under review), with placement according to qualifications and age, and with superannuation benefit.

The successful candidate will be expected to take up duty on October 1, 1979.

Further particulars may be obtained from the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh, with whom applications (six copies), giving the name of two referees, should be lodged not later than April 10, 1979. Please quote Reference 1028. 9998(A)

Two Research Assistants are required to work on

- (1) The biochemical aspects of the nitrogenous changes during the ensilage of grass. (Ref. ARC/18N).
- (2) Nitrogen metabolism in young chicks consuming microbial protein and nucleic acids. (Ref. ARC/19N).

Candidates should have a good Honours degree in Biochemistry, Biological Sciences, Agricultural Science or equivalent.

Salary initially £3,384 per annum.

Application forms and further particulars can be obtained from the Secretary, Edinburgh School of Agriculture, West Mains Road, Edinburgh EH9 3JG.

Closing date for receipt of completed applications—April 7, 1979. 7(A)

UNIVERSITY OF STRATHCLYDE

Applications are invited for a

LECTURESHIP

in the DEPARTMENT OF MATHEMATICS

Preference will be given to those candidates who have a research interest in applied analysis. Applicants with other interests will, however, be considered.

Salary scale: £3,883 to £7,754 (under review) with placing according to qualifications and experience. Superannuation benefit.

Application forms and further particulars (quoting 13/79) and enclosing a self-addressed envelope (9in x 4in), may be obtained from the Academic Appointments Officer, University of Strathclyde, Royal College Building, 204 George Street, Glasgow G1 1XW, with whom applications should be lodged by March 21, 1979. 15(A)

UNIVERSITY OF STRATHCLYDE DEPARTMENT OF APPLIED MICROBIOLOGY PROFESSOR IN APPLIED MICROBIOLOGY

Applications are invited from suitably qualified persons for full-time appointment to the Professorship in Applied Microbiology which will become vacant on September 30, 1979 on the retirement of Professor E. O. Morris.

The post will be remunerated within the Professorial range for universities with U.S.S. benefits.

Application forms and further particulars (quoting 12/79) may be obtained from the Registrar, University of Strathclyde, Royal College Building, 204 George Street, Glasgow G1 1XW, with whom applications must be lodged by April 6, 1979. 16(A)

GERMAN CANCER RESEARCH CENTER HEIDELBERG

Institute of Virus Research
(Prof Dr H. C. Kaerner)

A position is vacant for one year starting June 1, 1979 for a research assistant. Applicants are invited with experience on protein biochemistry and virology. This appointment will carry a salary on scale of BAT. For further details please contact German Cancer Research Center, Administration, Im Neuenheimer Feld 280, 6900 Heidelberg. 53(A)

POSTDOCTORAL POSITION

Biochemist, Bio-inorganic Chemist or Physical Chemist with interests in quantum biology. Research on spin-spin magnetic interactions in reactive coenzyme B₁₂. Experimental experience with metallo-enzymes or coenzymes preferred, and interests in quantum chemical methods will be helpful. Salary \$12,000. Renewable. Write: Dr R. E. Coffman, Department of Chemistry, University of Iowa, Iowa City, Iowa 52242, U.S.A. The University of Iowa is an equal opportunity and affirmative action employer.

51(A)

UNIVERSITY OF KENT AT CANTERBURY RESEARCH ASSISTANT IN MICROBIOLOGY

Applications are invited for the post of Research Assistant to work on a project supported by the Agricultural Research Council concerning the breakdown of cellulose in soil, particularly as it applies to the spatial relationships between microorganisms, enzymes, substrates and soil particulates, under the supervision of Dr R. G. Burns. The appointment is tenable for three years and a suitably-qualified applicant would have the opportunity of registering for a Ph.D. degree. Applicants must have, or expect to obtain, a first or upper second class honours degree in microbiology, biochemistry or a closely-related subject. Salary range £3,384 to £3,883. Particulars and application forms may be obtained from the Senior Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH, to whom completed applications should be returned by April 6, 1979. Please quote ref. A20/79. 8(A)

INSTITUTE OF CANCER RESEARCH: TECHNICIAN required at the Chester Beatty Research Institute, Fulham Road, London, SW3 to assist in studies on the development of systems for the delivery of toxic agents to specific targets. Candidates should possess an H.N.C., a university degree or equivalent in biochemistry. Experience in column chromatography and electrophoresis would be an advantage. The salary will accord with M.R.C. scales in the range £3,261 to £4,680 per annum plus £354 per annum London Allowance. Apply in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting ref. 301/B/60. 17(A)

New Zealand UNIVERSITY OF CANTERBURY Christchurch

Applications are invited for the following position:

LECTURER IN ENVIRONMENTAL SCIENCES (RESOURCE MANAGEMENT)

Preference will be given to applicants who hold a higher degree in resource economics, have varied and practical experience in resource management and have a commitment to teaching.

Applications close on **April 30, 1979**. The salary for Lecturers is on a scale from NZ\$11,894 to NZ\$14,615 per annum.

Particulars, including information on travel and removal allowances, study leave, housing and superannuation, may be obtained from the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF. 63(A)

Department of Biochemistry TWO POSTDOCTORAL RESEARCH ASSISTANTSHIPS

Applications are invited for two S.R.C. supported Postdoctoral Research Assistantships (Grade 1A) to participate in research programmes concerned with NMR studies in biological systems.

1. **One person appointed** will join a group under the direction of Dr I. D. Campbell and Sir Rex Richards and will be involved in developing the application of a 470 MHz NMR instrument to a variety of biochemical problems of interest to the Oxford Enzyme Group. This position is for two years and preference will be given to a candidate with a background in physics or physical chemistry with some interest in NMR techniques.

2. **The second appointment** is for three years. The person appointed will join the group under the direction of Drs G. K. Radda and D. G. Gadian concerned with studies of perfused organs (heart, kidney and muscle) by NMR and biochemical techniques. Persons with a background in physiology, biochemistry or chemistry will all be considered.

Both positions are available from October 1, 1979 and are on a salary scale of £3,883 to £4,882 per annum, dependent on age and qualifications, with U.S.S. superannuation benefits.

Applications should be sent to the Administrator, Department of Biochemistry, South Parks Road, Oxford OX1 3QU before March 31, 1979 from whom further particulars may be obtained. 36(P)

UNIVERSITY OF AUCKLAND DEPARTMENT OF CELL BIOLOGY POSTDOCTORAL FELLOWSHIP

The Molecular Genetics group in the Department of Cell Biology is studying plasmid DNA replication mutants, and has a position available for studies on plasmid replication proteins. Experience in enzyme purification and polyacrylamide gel electrophoresis techniques would be an advantage but consideration will be given to applicants with other, relevant, backgrounds. The position is for one year, starting on or after May 1, 1979. The salary will be \$8,400, and a return air fare is provided. Further particulars are available from Professor P. L. Bergquist or Dr H. E. D. Lane, Department of Cell Biology, University of Auckland, Private Bag, Auckland, New Zealand, to whom applications, together with a curriculum vitae and the names of two referees, should be addressed. 32(E)

QUEEN MARY COLLEGE University of London CHEMISTRY DEPARTMENT Applications are invited for a POSTDOCTORAL RESEARCH FELLOWSHIP

for work with Professor R. Bonnett (in collaborations with St Mary's Hospital Medical School) on the development of tetrapyrrole photo-sensitisers. The project would suit an organic chemist with experience in heterocyclic synthesis, but an interest in biochemistry and photochemistry would be an advantage. Starting date as soon as possible.

Salary in range £4,359 to £4,858 per annum (under review, including London Allowance).

Please apply by letter giving age, qualifications, experience and names of two referees to The Registrar (N), Queen Mary College, Mile End Road, London E1 4NS. 62(E)

UNIVERSITY OF ALBERTA, Department of Biochemistry. Postdoctoral Fellowship for recent graduate at a salary of \$12,200 (first year), \$13,350 (second year) to do research on the biological control of glycogen metabolism and/or structure-function relationships in phosphorylase. Write Dr N. B. Madsen, Department of Biochemistry, University of Alberta, Edmonton, Canada T6G 2H7. 38(E)

HOWE SENIOR RESEARCH FELLOWSHIP

Applications are invited by the Council of the Royal Society for the Howe Senior Research Fellowship, established from the Mr and Mrs R. L. Howe Bequest for the promotion and encouragement of scientific research. On this occasion applications are restricted to those working in the fields of fundamental or applied biological science. The appointment will be tenable in any appropriate university department or research institution in the United Kingdom approved by the Council of the Royal Society. Candidates, who must be citizens of the United Kingdom or the Commonwealth, must supply the usual personal details and give two referees. Testimonials will not be considered. The subject of the proposed research and where it would be done, together with the name of the head of the department, whose consent should first be obtained, must be stated.

The appointment, which will be subject to the Society's general regulations governing research appointments, will be tenable for five years from October 1, 1979 (or another date to be arranged) and may be renewable for successive five-year periods until the end of the academic year in which the holder becomes 65. Applicants should preferably be under 45 on October 1, 1979. The stipend scale will be £8,031 to £252 to £8,787 to £249 to £9,036 per annum, and the point of entry will be determined by Council. Superannuation benefits will be provided. Some provision for research expenses will be available.

Applications should be made on forms to be obtained from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1W 5AG, and returned by April 30, 1979. 26(E)

UNIVERSITY OF DURHAM DEPARTMENT OF PHYSICS

Applications are invited from graduates, preferably with Ph.D. in the field of High Energy Astrophysics, for a

POSTDOCTORAL SENIOR RESEARCH ASSISTANTSHIP

tenable for three years from as soon as possible. The successful candidate will join a research group working in experimental GAMMA RAY ASTRONOMY and should have some experience with balloon borne experiments. Salary on National Research Range 1A £3,883 to £6,555 (under review) plus superannuation.

Applications (three copies) naming three referees should be sent by March 26, 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. 9956(P)

ST PETER'S COLLEGE OXFORD JUNIOR RESEARCH FELLOWSHIP IN MEDICAL SCIENCES

St Peter's College, Oxford, proposes to make an appointment from October 1, 1979 to a Sidney Perry Junior Research Fellowship in Medical Science. The Fellowship, which is for research in clinical or non-clinical medical science, is open to non-medical as well as to medical graduates, and will be tenable for a period of two years and renewable for a third.

Salary £3,000 per annum. Further particulars available from the Master, St Peter's College, Oxford. Closing date for applications April 27, 1979. 89(E)

RESEARCH POSTS AT CAMBRIDGE

Applications are invited for two postdoctoral research positions in the Department of Applied Mathematics and Theoretical Physics, University of Cambridge, Silver Street, Cambridge (Tel: 0223 51645): (1) C.E.G.B. Fellowship in Fluid Mechanics, for theoretical or experimental research in an area of interest to C.E.G.B., tenure 3 to 5 years from October 1; (2) Research Associateship, for work on ocean acoustics with Dr B. Uscinski, tenure 3 years, in the first instance, from an early date. Further information available from Head of Department. 75(E)

FELLOWSHIPS & ASSISTANTSHIPS

UNIVERSITY OF BIRMINGHAM DEPARTMENT OF ANATOMY POSTDOCTORAL RESEARCH FELLOWSHIP

This post is for a study of the expression of myosin genes during early development and under pathological conditions, using monoclonal antisera. It is supported for three years by the M.R.C. and we would like to appoint as soon as possible. This is a chance to be in on the development of a unique combination of experimental techniques and to have the satisfaction of using them to tackle problems of fundamental scientific and clinical importance. The team is multidisciplinary and includes excellent technical backup. Salary is on the Research Fellow IA scale (£3,883 to £6,555) plus superannuation.

Your application should include a curriculum vitae, details of research experience and the names of two referees. Send it to the Assistant Registrar, Faculty of Medicine, University of Birmingham, Birmingham B15 2TJ by April 13, 1979 quoting reference RF/ANT/179 or talk to Dr S. Salmon on (021) 472 1301 ext. 2093. 81(E)

JUNIOR RESEARCH FELLOWSHIP IN CHEMISTRY

The College proposes, if a suitable candidate presents himself or herself, to elect a Junior Research Fellow in Chemistry for a period of three years as from October 1, 1979. The Fellowship is open to men and women pursuing research in any branch of Chemistry, and the Fellow elected may, with his or her consent, be assigned some share in the tutorial work of the College (provided that the total teaching involved shall not exceed six hours per week). Candidates are normally required to be under the age of 30 on January 1 in the year of election (ie 1979).

The stipend of a Junior Research Fellow is currently £3,325 per annum with superannuation, but this is now under review. In addition, the Fellow will be assigned rooms in College free of charge, and be provided with free meals. If the Fellow is married, a housing allowance of £350 may be payable in lieu of rooms.

Applications should reach the College Secretary, from whom further details may be obtained, not later than April 10, 1979.

Balliol College, Oxford OX1 3BJ. Oxford 49601. 85(E)

**BRITISH DIABETIC ASSOCIATION
LAWRENCE RESEARCH FELLOWSHIP**

SUBJECT: DIABETES MELLITUS

ELIGIBILITY: Open only to UK residents. Candidates must be appropriately qualified in medicine or science. **VALUE:** Appropriate point on NHS or university scale up to registrar (or equivalent university) grade. **TENABLE:** In any approved institution in UK, for 2 years. **OTHER INFORMATION:** Awarded for independent research. **NUMBER:** Two offered, normally every two years. (Offered for 1979/80.) **PARTICULARS:** Available from Secretary-General, British Diabetic Association, 10 Queen Anne Street, London W1M 0BD. Tel: 01-323 1531.

CLOSING DATE: April 18, 1979.

29(E)

**THE OPEN
UNIVERSITY**

Faculty of
Science

**Research Assistantships
in Chemistry**

Applications are invited for full-time Research Assistantships in Chemistry, tenable from 1st October 1979 or before for three years, to work in the following subject areas:

Photochemistry of peptides and its relevance to chemical processes concerned with the origin of life; the investigation of energy transfer between carbonyl compounds and aromatic acceptors using laser flash photolysis; pulsed NMR spectroscopy in the investigation of ion-ion and ion-solvent interactions; the development of new synthetic methods based on organosilicon chemistry for the synthesis of compounds of pharmaceutical interest; iron-sulphur clusters as models for biological electron transfer agents; synthesis, X-ray diffraction, electron spin resonance and nuclear magnetic resonance.

Applicants should possess a good honours degree in chemistry or an equivalent qualification. Salary will be within the range £3,384 to £3,883 p.a. on the Research Assistant 1B scale.

Application forms and further particulars are available from The Recruitment Office (JD3813/4), The Open University, P.O. Box 75, Walton Hall, Milton Keynes, MK7 6AL or telephone Milton Keynes 63404; there is a 24 hour answering service on 63868

Closing date for applications:

April. 20 1(P).

**UNIVERSITY OF HULL
DEPARTMENT OF
APPLIED PHYSICS/PHYSICS**

Applications are invited for three research fellowships, which are immediately available, for a period of up to three years.

Department of Applied Physics

1. A research fellow is required to measure the frequency characteristics of the current generation of pulsed O₂ lasers and to devise ways of improving their frequency stability using techniques such as hybridisation and injection.

2. A research fellow is required to work on the use of tunable multi-atmosphere, molecular gas lasers for the remote sensing of trace gases in the atmosphere.

Department of Applied Physics/Physics
3. A research fellow is required to investigate the use of ion implantation for fabricating fast, photo-voltaic, infrared detectors in materials such as HgCdTe.

These fellowships are suitable for graduates in Physics, Applied Physics, Electronic Engineering with at least three years' research experience in relevant fields.

Salary: The starting point will be within the scale £3,883 to £4,382 per annum (under review).

Applications should give full details of education, qualifications and research experience, together with the names of two referees, and should be sent by March 31, 1979 to Dr E. L. Thomas, Department of Applied Physics, The University of Hull, Hull HU6 7RX from whom further details may be obtained. 23(E)

**UNIVERSITY OF
STRATHCLYDE
PROJECT MASS—TEAM
RESEARCH IN MARINE
TECHNOLOGY**

Applications are invited from suitably-qualified graduates in Metallurgy (with an interest in Welding) or from Postgraduates in Welding Technology for a RESEARCH ASSISTANTSHIP in the DEPARTMENT OF METALLURGY to join an existing multi-disciplinary research team involving six departments in the University to work on the challenging problems associated with underwater maintenance activities. The appointee will be required to research in Underwater Welding problems in relation to offshore maintenance activities.

Project MASS has been initiated by the University of Strathclyde as a positive contribution to underwater maintenance research and is supported by a major grant from the Science Research Council. The work has the active backing of the Marine Industry.

Appointment to commence as soon as possible and initially until September 30, 1980 with the exception of extension subject to the agreement of both parties.

Commencing salary on Range 1A (£3,883 to £6,555) of the national salary structure for research and analogous staff, depending on age, qualifications and experience. Superannuation benefit.

Application forms and further particulars (quoting R10/79) may be obtained from the Academic Appointments Officer, University of Strathclyde, Royal College Building, 204 George Street, Glasgow G1 1XW, with whom applications must be lodged. 14(P)

**UNIVERSITY OF
STRATHCLYDE**

Applications are invited for the following research posts in the DEPARTMENT OF PURE AND APPLIED CHEMISTRY, available in October, 1979 in biologically oriented ORGANIC CHEMISTRY.

1. A POSTDOCTORAL RESEARCH FELLOWSHIP financed by S.R.C. for a period of two years to research on the Scope and Mechanism of Selective Hydroxylation by Alkyl-substituted Chelates of Iron.

2. A POSTDOCTORAL RESEARCH ASSISTANT financed by M.R.C. for a period of three years to research on the Synthesis and Evaluation of Potential GABA-mimetic Substances.

Appointments on Range 1A of the national salary structure for research and analogous staff, with a commencing salary on the scale £3,883 to £4,382 per annum with placing according to qualifications and experience. Superannuation benefit. Appointments will commence from October 1, 1979 or as soon as possible thereafter.

Written applications (quoting R9/79) with names and addresses of two referees should be submitted to Dr C. J. Suckling, Department of Pure and Applied Chemistry, University of Strathclyde, 295 Cathedral Street, Glasgow G1 1XL, from whom further information can be obtained. 13(E)

STUDENTSHIPS

**UNIVERSITY OF
STRATHCLYDE**

DEPARTMENT OF
PURE AND APPLIED
CHEMISTRY

**RESEARCH IN
ORGANIC CHEMISTRY**

Applications are invited for the following research post in biologically oriented organic chemistry available in October 1979.

Potential Chemotherapeutic Agents based upon Latent Irreversible Inhibitors or Dehydrogenases. S.R.C. C.A.S.E. Studentship in collaboration with Wellcome Research Laboratories.

Applications with names and addresses of two referees should be submitted to Dr C. J. Suckling, Department of Pure and Applied Chemistry, University of Strathclyde, 295 Cathedral Street, Glasgow G1 1XL, from whom further information may be obtained. 12(F)

GRANTS

**UNIVERSITY OF LONDON
GRANTS FOR RESEARCH**

Applications are invited from members of the University and teachers in Schools of the University for grants from the Central Research Fund to assist specific projects of research and for the provision of special materials and apparatus. Grants are not made for normal maintenance.

Applications must next be received not later than March 31, 1979. Forms of application and further particulars may be obtained from the Secretary to the Central Research Fund, University of London, Senate House, London WC1E 7HU. 61(H)

COURSES

**UNIVERSITY OF BRISTOL
M.Sc. (MEAT SCIENCE)**

This course occupies one calendar year and leads to the degree of M.Sc. (Meat Science) by examination and dissertation. Candidates should have either an honours degree in the biological sciences or a degree in veterinary science. Applicants with other qualifications, if combined with previous industrial research or experience, may also be considered.

The course provides a systematic programme of study at an advanced level covering the whole field of meat science. Instruction will be provided by the staffs of the University School of Veterinary Science and of the Agricultural Research Council Meat Research Institute, which are both situated on the University's Estate at Langford, about 14 miles south of Bristol. Accommodation is available in halls of residence.

Starting with the production of meat animals, the course extends through the scientific bases of all the operations involved on the production of meat and meat products, and includes consideration of the economics of the industry and of its controlling legislation. The objectives of the course are to equip graduates to apply the principles of meat science within the industry, to operate effectively in posts with responsibility for its legislative control or to provide them with the foundation for a career in meat research.

For further particulars please apply to:

The Registrar and Secretary,
(ref CYF),
University of Bristol,
Senate House,
Bristol BS8 1TH. 5(D)

**UNIVERSITY OF LONDON
ROYAL POSTGRADUATE
MEDICAL SCHOOL**

**M.Sc. DEGREE COURSE
IN EXPERIMENTAL
PATHOLOGY (TOXICOLOGY)**

Applications are invited for the above one-year, full-time course which is being offered from October 3, 1979.

Applicants should possess a first degree in medicine, veterinary medicine or appropriate science subjects.

A limited number of M.R.C. course studentships are available.

Further details and application forms are available from the

Assistant Secretary (Registrar)
Royal Postgraduate Medical School
Hammersmith Hospital
Du Cane Road
London W12 0HS
(Tel: 01-743 2030, ext. 263)

An unconventional balance with an extra measure of accuracy

Mettler DeltaRange breaks through the boundaries that used to restrict the capacity/accuracy ratios of conventional weighing instruments. And Mettler PC electronic top-loading balances are equipped with this new *Mettler DeltaRange* feature.

Just press the control bar of the Mettler PC4400, for example, and you get a 400 g fine range with readings that are 10 times as accurate as those in the coarse range. And you can do it as often as you wish, at any point of the entire weighing range. That is to say, whenever and wherever a 0.01 g readability is needed. On a balance that has a capacity of no less than 4000 g!

In practice, this means that you can use a heavy container to accurately weigh in as many components as you want. Or that you can weigh one time on a lightweight paper, the next time into a heavy recipient; both times with results that are readable to the second decimal place.

To learn more about the many things your Mettler PC balance can do for you with outstanding speed and precision, send for our detailed brochure. It's an eye-opener.

Mettler
Precision you can depend on

Aims and Scope

The Journal of Biochemical and Biophysical Methods offers researchers a unique opportunity to keep abreast of the development of methods used to solve biological problems. Providing a medium for the rapid publication of research papers and critical, concise reviews concerned either with new methodology, or with the significant modification of existing techniques, the journal will be essential reading for the laboratory worker needing to keep up-to-date with methods, or the specialist interested in method development. The scope of the journal is broad, encompassing all methodological aspects of biochemistry, biophysics

and molecular biology. Although articles should be written in sufficient detail to allow easy verification they should also be intelligible to a broad scientific audience. In addition the journal will publish a section of short notes describing improvements in methods which, though significant, do not warrant a full-length research paper. Short review articles dealing with recent developments in a particular method or technique that are of interest to a broad scientific audience will also be published.

The essence of the journal is high quality and rapid publication.

The following contents of Volume I, Issue I give an indication of the broad scope and authoritative nature of the journal

Determination of small differences in buoyant density of macromolecules by analytical density gradient equilibrium centrifugation

P. Nieuwenhuysen (Antwerp, Belgium)

Rapid pH and μH^+ jump by short laser pulse

M. Gutman and D. Huppert (Tel Aviv, Israël)

The application of Fourier transform infrared transmission spectroscopy to the study of model and natural membranes

D. G. Cameron, H. L. Casal and H. H. Mantsch (Ottawa, Canada)

Chromatographic properties of Sephacryl S-300 Superfine

I. Johansson and H. Lundgren (Uppsala, Sweden)

Human globin chain separation by isoelectric focusing

P. G. Righetti, E. Gianazza, A. M. Gianni, P. Comi, B. Giglioli, S. Ottolenghi, C. Secchi and L. Rossi-Bernardi (Milan, Italy)

Fluorography of tritium-labelled proteins in immunoelectrophoresis

O. Norén and H. Sjöström (Copenhagen, Denmark)

Short note: Automated scanning of ^{14}C on polyacrylamide gel

R. P. Magnusson and A. Jackiw (Bethesda, MD. and Detroit, MI., U.S.A.)

Pubblicazioni della Stazione Zoologica di Napoli

The Zoological Station of Naples is pleased to announce that its journal *Pubblicazioni della Stazione Zoologica di Napoli* (P.S.Z.N.) will resume publication. The P.S.Z.N. will be divided into two sections: I. Marine Ecology and II. History and Philosophy of the Life Sciences.

Marine Ecology is devoted to promoting, through the recent move marine biologists have made towards its intimate environment, scientific knowledge of the living sea. Contributions are therefore invited from all those disciplines that promote ecological understanding of marine natural systems, particularly by direct observation or by *in situ* experiments, from the single species to the overall system of the ocean. Marine Ecology is published twice yearly, in March and October. The first volume will appear in March, 1980. Editor-in-Chief: R. Riedl, Zoological Institute, Währingerstrasse 17/A, 1090 Vienna, Austria.

If philosophical reflection can and must guide historical investigation, it is not less true that the philosophy of science can and must feed itself upon and allow itself to be modelled by historical research. H.P.L.S. welcomes original contributions on historical development, the social, philosophical and epistemological implications of the life sciences and techniques. The main concern of the journal is modern western scientific thought, but there is no limit regarding chronology, or the scientific nature of the subject or its cultural area. H.P.L.S. is published twice yearly, in June and December. The first volume will appear in June, 1979. Editor-in-Chief: M. D. Grmek, 10, Rue de Savoie, 75006 Paris, France.

Further information concerning editorial policy can be obtained from the Editorial Office: Stazione Zoologica, Villa Comunale, 80121 Naples, Italy. Publisher: Leo S. Olschki, P.O.B. 66, 50100 Florence, Italy, to whom also requests concerning back issues should be addressed.

Circle No. 10 on Reader Enquiry Card.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; $\exp(a)$ is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined on 258, 1 (1975) and 264, v, 11 Nov. (1976).

Chemical warfare: rearmament or disarmament?

THIS past week a party of diplomats from a wide range of countries has been flying around Britain looking at the demolition of a chemical weapons factory in Cornwall and inspecting the Birmingham premises of a manufacturer who handles phosphorus compounds. This somewhat unusual exercise is part of an Anglo-German effort to put the problems of chemical disarmament in clearer context. But despite occasional flurries of activity, indeed despite draft treaties tabled with the Conference of the Committee on Disarmament, there is as yet nothing like unanimity amongst nations on what sort of agreement would be acceptable, and there are substantial pressures, most notably in the United States, for chemical rearmament.

Biological weapons were effectively banned by a 1972 convention in which all major states agreed 'never in any circumstances to develop, produce, stockpile or otherwise acquire or retain microbial or other biological agents, or toxins . . .'. Additionally the Geneva Protocol of 1925, also widely adhered to now, prohibits the use in war of 'asphyxiating, poisonous or other gases' although this protocol does not close the door on research and development, production or stockpiling of chemical weapons against possible first-use by another nation. It is this lack of prohibition on 'defensive' chemical weaponry which has allowed the development of mustard gas, hydrogen cyanide and nerve agents, particularly sarin, soman and VX, together with the means of delivery. It is known that the Soviet Union, France and the United States maintain stocks of chemical weapons; whether any other nation, particularly in the Middle East, possesses them is unclear. However, material captured during the 1973 Middle-East War showed that the Soviet Union was prepared to supply allies with the wherewithal to fight in a toxic environment.

Since then the United States has been taking serious stock of its ability to cope with a chemical warfare attack and, if necessary, to retaliate in kind. Binary weapons, comprised of two harmless constituents which mix in the missile only after launch, are being discussed seriously (*Nature*, June 15, 1978, page 481). And this past year two important documents have been published: a plea for the US government to give chemical warfare much more attention ('The Neglected Threat of Chemical Warfare, by A. M. Hoeber and J. D. Douglass, in *International Security*, Vol. 3, No. 1) and the proceedings of a conference which looked at the wide spectrum of possibilities for responding to Soviet activity, in particular by arms control measures (*Chemical Weapons and Chemical Arms Control*, Matthew Meselson, ed., Carnegie Endowment, 11 Dupont Circle, Washington, DC).

The most likely venue for any chemical attack would be central Europe, and the most likely target would be small pockets of soldiers, or military installations. A chemical strike against an airfield might be particularly effective. There are clear similarities between chemical and tactical nuclear weapons, but, of course, an obvious distinction is

that once the nuclear road had been taken in a war the possibilities of escalation would be almost infinite.

This poses a dilemma: if the Soviet Union were to lead with a chemical attack, would NATO respond in kind or would it use tactical nuclear weapons? There is a fair amount of disagreement about the answer. The United States maintains large stockpiles (almost all back home at present) and is busy equipping its soldiers with new protective clothing; its army would undoubtedly like to have the capability of responding in kind. On the other hand West Germany does not store chemical weapons and does not train personnel to use them. Britain too does not maintain retaliatory capability, relying on nuclear deterrence, but also stresses the value of anti-chemical defences (having been successful in selling protective clothing to her allies).

There is even disagreement about the size of the Soviet threat. Hoeber and Douglass speak of Soviet superiority over the United States being of 'two or three orders of magnitude', making chemical warfare, even uncoupled from nuclear attack, 'a major contingency for which the Soviet Union plans'. On the other James Leonard, an arms controller, speaks of a *de facto* chemical disarmament in Europe and says he has never been satisfied that there was a significant Soviet capability to wage a chemical war, whilst Julian Perry Robinson, of Sussex, asserts that the threat of Soviet chemical weapons 'can at most be marginal'. Faced with a diversity of assessments (based, it must be said, on desperately little hard data) and faced with an alleged aversion, even by military men, to contemplating the use of such unchivalrous means of warfare, is it possible to neutralise the chemical weapons threat, not by pressing on with bigger and better stockpiles, or by improving protective clothing, but by arms control measures?

The military man will say: yes, but first have a strong retaliation capability as a bargaining chip; on the other hand the arms controller might even propose unilateral measures of disarmament to build confidence. Between nations, however, the sticking point is the difficulty in achieving any satisfactory degree of verification. The Soviet Union's favoured brand of monitoring is self-monitoring. Western proposals are much tougher on international safeguards, such as on-site inspection. A resolution of these differences does not seem imminent.

In the meantime, what does Britain do? At present her initiatives seem to be in promoting chemical defence and arms control. But this supposes that retaliation by nuclear weapons will be effective and acceptable. Could Britain start work on chemical offensive weapons again? Not under a Labour government, but might a Conservative government sanction modest activities? We simply don't know. Public discussion of chemical warfare is just about non-existent in Britain; presumably in the restricted circles of ministers, generals and top civil servants some people are thinking hard about options. It is time the debate was widened. □

Einstein: disagreement delays publication of collected works

David Dickson reports on the circumstances that have delayed the publication of Albert Einstein's collected writings, which fill 28 file drawers at Princeton University

PLANS to produce a multi-volume edition of Albert Einstein's published and unpublished writings are virtually at a standstill following the failure of the trustees of Einstein's estate, the Princeton University Press, and the project's editor to agree on mutually acceptable terms under which the editorial work can proceed.

Already a project funded by the National Science Foundation, whose initial purpose was to prepare the papers for publication, has had to be revised to the more modest goal of indexing and preparing duplicate copies of the papers. These are kept at the Institute for Advanced Studies in Princeton, where Einstein worked after coming to the USA.

There are no plans at present for the NSF to provide further support for the project after the current contract of the editor of the collected works, Professor John Stachel, expires on 14 July. Nor has the university press announced how it plans to pursue the project after this date.

The trustees of Einstein's estate, who have never refused access to the papers by "reputable scholars", have taken great care to ensure that the editorial work is carried out in a way that they feel would have met his approval. (Dr Otto Nathan, one of the two trustees, has expressed strong disapproval of the National Academy of Science's plan to erect a statue of Einstein in Washington, since he claims this is explicitly against the physicist's wishes).

However a number of physicists and historians of science, many of whom are reluctant to be quoted for fear of exacerbating the current situation, are concerned that the trustees have interpreted their responsibilities so rigidly as to restrict a full appreciation of Einstein's contribution to twentieth century science and thought.

Dr Paul Foreman, for example, organiser of a current exhibition on Einstein at the Smithsonian Museum in Washington, has expressed his regret that the trustees have refused, as a matter he claims of "unbending policy", to loan the exhibition letters and photographs from the estate.

Albert Einstein was a prolific writer on both scientific and non-scientific issues. During his lifetime he published 274 scientific papers and 332 papers of

a general content; these, and a large quantity of unpublished material, form the archives which currently fill 28 file drawers at Princeton University.

His correspondents range from scientists such as Erwin Schrodinger, Max Planck, Wolfgang Pauli and Marie Curie, to contemporaries in other fields, such as Sigmund Freud, Bertrand Russell, Franklin Roosevelt and George Bernard Shaw. And some of the letters, particularly to physicists, suggest further avenues of research which Einstein himself was unable to follow.

On his death in 1955, the literary rights to his papers passed to a trust, of which the two trustees are Helen Dukas, his secretary from 1928 to 1955, and Dr Otto Nathan, an economist and close friend who, like Einstein, came to the US as a refugee from Europe. (Under the terms of the will, the beneficiaries of the trust are Miss Dugas and Margot Einstein, his stepdaughter; eventually the estate will pass to the Hebrew University in Jerusalem).

Negotiations over the publication of the collected works began within weeks of Einstein's death. In 1971, the trustees reached an agreement with the Princeton University Press, which had expressed great interest in the project from the very start. And in 1976 the trustees and the press appointed Professor John Stachel, a physicist on leave from Boston University who has recently co-edited selected papers of Leon Rosenfeld, to be the editor.

In the same year, the university press submitted a grant proposal to the National Science Foundation, requesting \$787,300 over a five-year period to support editorial preparation for the multivolume project. This, they suggested, would be a "fitting monument" to Einstein, and would include all his published and unpublished writings in the original languages, with English translations of some of the more important works.

The foundation agreed to provide initial support to allow Professor Stachel to plan the editorial work, and to establish the general principles of editing the whole project. The foundation awarded \$80,000 towards this in 1977 and 1978. But difficulties soon arose in agreeing on a work plan that would be acceptable both to the

Prolific writer: 606 papers published

trustees and to Princeton University press.

Dr Nathan insisted, for example, that only the editor be allowed to handle the original documents, thus making it necessary for Dr Stachel to do much of the work that would otherwise have been done by research assistants. And other areas of disagreement arose over how the editorial work on the documents should proceed.

It soon became clear to the participants that it would be impossible to proceed with the preliminary editorial work plan that had been developed under the NSF grant, or to complete negotiations with the foundation on the initial five-year grant proposal (even though the plan had been endorsed by an editorial advisory board which met to discuss the situation early in 1978).

At the prompting of NSF's review panel, the university press and Professor Stachel approached the foundation again to support the completion of work on a duplicate archive and an index, to make sure that "when the time comes, the editing of the Einstein papers can proceed without the past year-and-a-half being wasted".

The trustees and the press wrote in a joint statement that a duplicate archive was "absolutely necessary for the continuation of the editorial work if we are able to proceed after 14 July 1979," but added that "if the work of editing *The Writings of Albert Einstein* should cease, one copy of the entire duplicate archive will be kept intact and unmarked so that a new editor, when appointed, could use it with confidence".

Work is now almost completed on the material for the duplicate archive being carried out under an NSF grant which runs out on 30 June; so, too, is the preparation of an index to all the

papers in the archives, the total number of which may be as high as 60,000. And Professor Stachel has also been able to contact many of those who were in correspondence with Einstein, asking for their comments on copies of letters which have been sent to them.

But there the matter rests. Mr Herbert Bailey, head of the university press, admits that the project has had "problems", and does not accept that it has gone into abeyance. "We have a lot of reasons to think that the project, on which we are as keen as we have always been, will go forward" he said last week; however he declined to reveal how the project will proceed after the NSF grant money, and Professor Stachel's contract, run out in the summer.

Dr Nathan is equally adamant that claims that the trustees have placed unworkable restrictions on how the editing work should proceed are "nonsense", and that the trustees "are being maligned" if such charges are being made.

He says that since a few days after Einstein's death the estate has been attempting to get a complete edition of the physicist's writings published, but that he has been "blocked again and again", and that he feels that "at the moment we do not know where we are going".

Historians of science are hoping that the stalemate can be resolved by some means (there are rumours of possible litigation, but these cannot be confirmed). No one disputes that the

collected works, when they are eventually published, will be a major contribution to twentieth century scholarship, helping to provide a far greater understanding of Einstein's role in the development of both modern science and the modern world; but few do not express frustration at the current impasse.

"When completed it will be—or should be—what historians and philosophers of science, and others, have been waiting for since Einstein died", Dr Jeremy Bernstein, professor of physics at Stevens Institute of Technology, and author of a biography of Einstein, wrote recently. "Not all this material is of great interest . . . but what matters is that it should be available." □

FDA scientists dispute ethics of testing laetrile

A SCIENTIST with the Food and Drug Administration has filed a "citizen's petition" against his agency in an attempt to prevent it from giving approval to clinical trials which the National Cancer Institute is planning to carry out on the controversial anticancer drug laetrile.

Dr Robert Young, a clinical oncologist with the FDA, echoing concerns which have already been expressed and debated within the NCI, claims that such trials would be in violation of accepted ethical codes since no firm scientific evidence yet exists that the drug has any beneficial effects.

Both the FDA and the US medical establishment maintain stiff opposition to the use of the drug, which is derived from apricot kernels and is currently taken by thousands of cancer patients in the nation. The agency has issued notices warning that laetrile is "worthless" and that its cyanide content in particular is potentially dangerous.

However despite this uncompromising stand, FDA commissioner Dr Donald Kennedy, previously professor of human biology at Stanford University, has come under pressure from those who argue that although previous studies do not provide any conclusive evidence that laetrile has a beneficial effect, neither is there sufficient evidence to rule out such an effect.

The clinical trials have been proposed by the NCI following a retrospective study of laetrile patients which the institute, having frequently rejected the idea in the past, agreed to carry out last year.

Over 90 cases claiming evidence of a beneficial effect of laetrile treatment were submitted in response to a nationwide appeal, and a detailed study of 67

of these by a panel of oncologists revealed six patients who had received laetrile as their primary treatment, and were judged to have had a clinical response.

Announcing the results of the study last autumn, the NCI said that these would not normally be sufficient to suggest that a drug merit clinical tests over other candidate drugs. However it added that "because of widespread public use and interest in laetrile, the NCI will proceed with plans to evaluate the drug".

Subsequently the institute filed an "investigational new drug application" (IND) with the FDA in December. And although the agency has taken considerably longer than normal to approve the application—there have been detailed discussions with the NCI both about the protocol for the experiment, as well as on technical details about the quality, stability and purity of the substance to be tested—this is expected to be granted within a few weeks.

Dr Young's objection to granting approval is that "there is not adequate scientific data that would justify the

test of the drug in human beings." In an interview with *Nature* last week he cited in particular the lack of evidence, accepted by the NCI, of the drug's efficacy in animal tests; and even the retrospective tests, he says, provides "no scientific data from which you can responsibly conclude that it was the taking of the drug that mitigated the disease".

In his petition, which Dr Young says reflects the feelings of a number of laboratory staff in the agency, he requests that laetrile should not be exempted from the provision of the Food and Drug Act, which require reports "adequate to justify the proposed clinical testing". And he criticises the agency for using a "sociopolitical argument", rather than a solid scientific case, to justify the trials.

If the FDA approves the cancer institute's IND, a six-month study will be carried out involving between 150 and 300 patients with different types of cancer; participation will be restricted to patients in whom all known therapies have been attempted.

Meanwhile the Supreme Court has agreed to rule on whether the FDA has the right to bar the use of laetrile as an anti-cancer drug, following the decision of a lower court that the need to show a drug is both "safe" and "effective" before being approved for sale or distribution does not apply to drugs used by terminally ill cancer patients.

In appealing the decision to the Supreme Court, the FDA has claimed that this ruling seriously limits its power to protect the public from unsafe and ineffective drugs, adding that it would be "virtually impossible to restrict the use of laetrile to the terminally ill".

"To the nearest apricot farm!"

Space shuttle: costs and technical delays raise political doubts

AFTER almost 10 years of preparation, technical delays and uncertainties are turning the final development stages of the National Aeronautics and Space Administration's Space Shuttle programme into something of a political cliffhanger.

A succession of last minute technical problems, although not unusual in a project as complex as developing a re-usable launch vehicle able to place and subsequently retrieve objects from an earth orbit, are receiving wide press attention and close public scrutiny. And Congress has already told NASA that, in a year of tight budgets, the agency cannot be guaranteed of receiving the extra \$185 million it has requested for covering the extra work involved. Current estimates of the cost are 8-9% higher than originally estimated in 1971. If granted, the additional money would take the total science budget for the financial year 1979 above a previously agreed ceiling.

If NASA does get the extra money, it is confident that Space Shuttle can be in orbit by the end of the year. Even though it publicly admits that the chances of meeting the planned 9 November launch date are "relatively low", it has criticised the National Academy of Sciences which suggested a launch date of April 1980, as being "unduly pessimistic".

But if NASA does not get the money—and the request is being closely scrutinised by the Senate budget committee, in particular since money for space research comes under the heading of discretionary funding—then the agency could be in deep trouble.

Under such circumstances, according to associate administrator John F. Yardley, the first manned orbital flight would be delayed an additional six to nine months. The delivery of production orbiters would be delayed up to one year, and this could seriously disrupt planned launch schedules.

Among the projects affected could be the European Space Agency's Spacelab, whose first launch is currently scheduled for August 1981. Initially planned for launching at the end of this year, cost increases for Spacelab—some made necessary by changes in the design of the Space Shuttle—have already exceeded the limit above which participating nations are entitled, if they wish, to withdraw.

Since being given the go-ahead by President Nixon in 1972, the Space Shuttle programme has had to run a continuous gauntlet of congressional criticism. Among past critics is Vice-

President Walter Mondale, today silent on the issue, but in 1972 claiming that the Shuttle was many times worse than supersonic transport "in the magnitude of its cost, in the folly of its concept, and thus in the damage to the country."

Such opposition has kept the research and development programme to a skeletal minimum, a far cry from the lavish spending on the Apollo moon programmes. Mr Yardley complains that requirements carried out in 1974, 1975 and 1976 have taken their toll, and that "further reductions in programme content are not considered possible".

Funding pressure has forced hard managerial decisions on NASA, and some of these were commented on by an *ad hoc* review group set up last year at the request of a senate committee by the National Academy of Sciences under the chairmanship of Dr Eugene E. Covert, professor of aeronautics and astronautics at Massachusetts Institute of Technology.

In an initial report last March, the committee pointed out that unlike previous programmes, the development strategy for the Shuttle programme as devised by NASA was "success oriented", and based on the assumption that each piece of development hardware and its subsequent verification test would succeed at the first attempt.

"It may be that this strategy has already saved time and money However, if or when malfunctions occur during the testing of the operational engine, new hardware may need to be designed, constructed and retrofitted, causing delays in the programme", the report said.

Such indeed has turned out to be the case. There have been problems, for example, both with the turbine blades and with the heat exchanger in the Shuttle engine—being developed by Rocketdyne—the latter being a component which the review group singled out for concern. And the temporary tiles which broke loose during a flight last week and damaged some of the fitting had been made necessary by un-

expected delays in fitting the permanent tiles—of which there are 5,000, each requiring 650 man-hours of work.

There have also been problems with weight. Design changes in the launcher vehicle have caused problems for, for example, the Galileo orbiter probe to Jupiter, planned for launch in 1982, but on present specifications now requiring 109% of the engine's theoretical thrust.

The big question now is how smoothly the rest of the pre-launch development programme goes. NASA admits that its present schedule is a "success oriented schedule with a minimum of contingency time", but adds that "it has been our experience in the past that such success schedules result in minimum cost and earliest actual dates",—in other words that even if unrealistic, planning for sooner rather than later helps to keep the pressure up.

The Covert committee is less optimistic. "We think it highly likely that there will be more problems before the first orbital flight", one member of the committee said last week. This sanguine perspective led the committee last month to recommend next spring as a more realistic date. NASA says that this is based merely on "intuitive feeling".

Meanwhile NASA officials are busy trying to persuade Congress to give them the extra money needed to let the shuttle programme proceed to its conclusion as planned. The supplemental request is being examined for Senator Muskie by the General Accounting Office of Congress. The 1980 request for NASA contains no new space science starts largely because of the pressure on Shuttle funding.

There is already talk of NASA possibly needing a supplemental to its 1980 budget, even though it may mean the agency coming back to Congress cap in hand. Ten years ago, the money would have been provided eagerly—today no-one is taking bets on the outcome.

West Germany: eyeball to eyeball over nuclear fuel reprocessing

NEXT week, critics and supporters of nuclear power will be meeting in Hanover, West Germany to analyse proposals to build a nuclear fuel reprocessing and waste disposal facility at a site 5 km from the East German border near the village of Gorleben in Lower Saxony. The forum for the analysis is to be a week of public hearings organised by the state government of Lower Saxony.

Twenty-five expert nuclear critics, 20 of them from outside West Germany, will face 25 nuclear supporters in a 'round table' discussion: an audience of 200 will listen in. The ostensible aim of the hearings is to inform the public and to help Ernst Albrecht, premier of the Lower Saxony government, decide whether or not to grant a licence for construction of the facility.

Already there are fears that the hearings will get off to a bad start. Some of the critics are suspicious of the state government's motivation for holding them: they think that pressure from the federal government means that construction of the plant is inevitable. They are also critical of the delay in deciding on a format for the hearings and of the lack of public information on them. Three weeks before them, the names of the 25 pro-nuclear experts had not been released, although the anti-nuclear names had been known for a long time.

Criticism has also been levelled at the way in which the 200 places in the audience have been allocated. Apparently about 100 places are to be taken by state and government authorities, 20 by representatives of the nuclear industry, 30 by the press, only three by members of local environmentalist groups and one by a representative of the district authority. The remainder are for members of parliament of Lower Saxony. With no spare places for interested members of the public and only 30 press places, it is argued, the hearings are not truly public.

The proposal under discussion is for the construction of a plant capable of reprocessing all of West Germany's spent nuclear fuel. It would include spent fuel storage ponds and plants for fabricating mixed oxide fuel, uranium finishing, vitrifying high-level radioactive waste as well as reprocessing 1,400 tonnes of spent fuel per year. Final disposal of all radioactive waste would also be on the site in salt domes a few hundred metres below the surface. The total cost is estimated at DM12,000 million.

The nuclear industry, amongst others, expects the decision reached by the Lower Saxony government over the licensing of the plant to be crucial to the future of nuclear power in West Germany. In the summer of 1977, the federal government announced that no new reactors could be licensed until the problem of disposing of spent nuclear fuel—*Entsorgung*—had been solved. Since then, reprocessing has generally been assumed as the only way of satisfying that condition. Unless an alternative can be found (and the nuclear critics hope to show next week that there is one) a veto of the reprocessing plant is expected to mean an end to the expansion of nuclear power in West Germany.

Plans for the proposed facility, or *Entsorgungszentrum*, were first submitted to the Lower Saxony government in March 1977, by DWK, a company set up by the West German utilities specifically to build it. At the same time, plans for the underground waste storage facility were submitted by the federal Physical-Technical Institute. A 3,000-page safety report, which accompanied the two applications, was examined by the Commission for Reactor Safety and the Commission for Radiological Protection, two advisory bodies to the federal Ministry for the Interior. In October 1977, both bodies published their comments on the safety report saying that they found it reliable and acceptable. The federal government, believing that the disposal of spent nuclear fuel was under control, began to talk about expanding the nuclear programme.

Meanwhile, local people in Gorleben started to protest about the proposal. They felt that the two commissions had been biased in their assessments of the safety report. In addition, DWK had started to try to purchase land from local landowners by offering them a very high price if they sold by a certain date. If they missed the dealing, DWK threatened to start expropriations procedures to procure the land for a much lower price.

To date only 40% of the land has been sold. Of the remaining 60%, the vast majority is owned by one man—Count Bernstorff, a remnant of the German aristocracy and prominent figure in the local landowner association (which has been very active in organising the protest).

At the beginning of 1978, the landowners association began to put pressure on the Lower Saxony govern-

ment to set up a committee of independent nuclear experts to review the proposals. After approaching one or two foreign experts to gauge support for the idea, the association drafted a list of experts it wanted to sit on a review committee. After elections in June of last year, when local environmentalist groups took 18% of the votes in Gorleben and 3.9% in the surrounding area, the state government agreed to invite the experts to spend 30 days producing their own report on the proposals and safety report.

In September 1978, 20 expert nuclear critics from France, Norway, Sweden, the UK and the US met in Hanover for the first time. By the beginning of March they had prepared a 2,200-page report and had submitted it to the Lower Saxony Ministry of Social Affairs. The report consists of eight chapters each prepared by different experts. The first chapter is a general introduction, the second discusses routine emission of radiation and radiological protection, the third accidents, the fourth safeguarding of fissile materials, the fifth the technical problems of reprocessing, the sixth waste management, the seventh final disposal and the eighth decommissioning. Among those taking part in the review were Walt Patterson and Amory Lovins of Friends of the Earth, Frank Barnaby of the Stockholm International Peace Research Institute, Paul Sieghart of the International Commission of Jurists and Professor O. Lindstrom of the Royal Institute of Technology, Stockholm.

Although the members of the review panel started work last September, they did not receive their contracts until the end of December. Several of them claim that during discussion of the terms of the contract they had requested that the report be published before the public hearings. However, the contracts said that the report had to be withheld from publication until 10 July.

A significant achievement of this action has been to increase dissatisfaction with the way the review and hearings are being run. The state government is committed to take some decision on the future of the reprocessing plant in May or June, before

the July publication date. Some feel this defeats the object of the review as a public information exercise.

More generally, there are feelings that the government would not seriously contemplate calling a halt to the plant whatever the outcome of the hearings. The formal licensing procedure was begun in 1977, and although it has now almost ground to a halt,

it is thought that the Lower Saxony government would be unlikely to stop it abruptly. Even if licensing were now to proceed as fast as possible, it would be 1981 before it were completed. What seems most likely, therefore, is a 'vague' decision.

Whilst the critics and nuclear industry are discussing the Gorleben proposals next week, the people of Gorle-

ben, who do not have an invitation to the hearings, will be taking part in a demonstration march from Gorleben to Hanover. The Lower Saxony government is expecting the affair to be violent for it is reported that 100 prisoners have been transferred from local gaols to make way for the recalcitrant villagers.

Judy Redfearn

US panel approves research on *in vitro* fertilisation

THE US is likely to end a three-year moratorium on research on the *in vitro* fertilisation of human ova following the conclusions of a federal advisory board that there are no ethical objections to such research being carried out on federal funds.

The ethics advisory board was established last year by Mr Joseph A. Califano Jr, Secretary of Health Education and Welfare, to advise him on whether work along the lines of the British research workers Mr Patrick Steptoe and Dr Robert Edwards should be permitted to proceed in the US. On reaching its conclusion, however, the board declined to say whether it felt that such research should in fact receive federal support.

Having heard evidence from scientists, religious leaders, anti-abortion groups, infertile couples and others, the board recommended that the work should be permitted provided that a number of requirements were met. These include:

- that research be aimed primarily at establishing the safety and efficacy of procedures for *in vitro* fertilisation;

- that no embryo be sustained in laboratory conditions for more than 14 days;

- that both the participants in the research—which would include clinical trials—and the public be informed if there is any evidence that such research is having ill-effects.

Although these provisions, and the decision to recommend that the moratorium be lifted, were agreed unanimously by the 13-member board of lawyers, scientists and others, there was less agreement on the priority which *in vitro* fertilisation should be given as a research topic.

Several members suggested that it should come low on the national priority list, and one suggested that the government should not fund any such research. Others disagreed, claiming that the research might soon become a "high priority" if there is wide demand from doctors to adopt the new techniques.

The board therefore agreed not to recommend whether HEW should fund such research, accepting that in addition to ethical concerns, this also

raised scientific, economic and political considerations.

Funds for 'test-tube baby' research have been held up for more than three years in anticipation of the advisory board's report, although the members of the board were only announced last summer. Congress placed a total ban on all research involving fetuses in 1974, and although this ban was lifted one year later, the position with respect to *in vitro* fertilisation has remained uncertain.

The only application at present lodged with HEW for carrying out such research is from Dr Pierre Soupart of Vanderbilt University, who has been waiting since 1975. The ethics board suggests that Dr Soupart's application now be forwarded to the National Institutes of Health for scientific review.

The board also recommended that the secretary of HEW should encourage, and even possibly provide financial support for, the development of a model law outlining the legal status of children born as a result of *in vitro* fertilisation. □

Spanish universities unhappy with new autonomy law

SPAIN'S universities have long sought autonomy from government control—and they should achieve it as one of the first actions of Spain's new government. But it may not prove to be the prize once dreamed of.

The first duty of the new government will be to debate the laws outlined in Spain's new constitution; and one of these is a law granting university autonomy: but was the law well-framed?

Government officials, political parties, and university professors are unanimous in their belief that the universities need rapid attention: they suffer from overcrowding, graduate unemployment, poor teaching, and lack of research. Furthermore the universities do not have the power to distribute their own funds, to select their staff or students, or to organise their own teaching. Every decision has to pass through the central Ministry of Education.

Even before the Constitution was written and approved, the Ministry of Education and Science was preparing a

draft of a law for autonomy, and—despite strong criticism—it was forced through the Council of Ministers and entered parliament the day before its dissolution.

The law as it has been published is a long and in certain aspects detailed text. It deals at length with the structure of university management (Senate, Rector, etc.) and with the teaching staff; but it deals only briefly with the administrative staff and research.

Two changes introduced by the new law are financial autonomy, and the separation of academic and economic authorities. The law also allows the existence of private universities, which would interest certain religious societies.

But many points in the law have received criticism from the universities—such as the system of selection of teaching staff, which remains almost untouched. For example, an aspirant to full professorship (Catedrático) must spend three years as associate professor (Adjunto), a regulation which bars many non-academic professionals

whose expertise might benefit a university.

The law also describes—in detail—the composition of the various university institutions, making it difficult to apply to any new university, while some fundamental problems—such as the role and funding of research, the selection of students, and increases in funding or staff, are left untouched.

The parliament formed after the elections held on 1 March is almost identical to the previous one, and the centrist party will most likely be charged with the task of forming the new government. It will probably back the existing law as created by the Ministry.

In the universities it is hoped that the law may produce some positive changes, but it is regretted that a general debate and a deep rethinking of the function of the universities in Spain has not taken place. If the law is approved as it is, it may be felt by the teaching community as a lost opportunity.

Pedro Puigdoménech

Bulgarian industry tackles environment

BULGARIAN industry is involved in a crash programme of anti-pollution measures, according to Mr Vordan Tsvetanov, Deputy Minister of Machine Building, who visited Britain recently.

The visitors, who included the Minister of Machine-Building, Mr Toncho Chakarov, came to discuss increased trade and cooperation in internal combustion engines, hydraulics and electro-technical equipment. Although pollution problems did not enter specifically into these discussions, Mr Tsvetanov told *Nature* that Bulgaria was making "wide use" of the anti-pollution experience of other countries and was naturally very interested in possible cooperation "especially as far as production facilities are concerned".

According to Mr Tsvetanov, new industrial complexes in Bulgaria pose little threat to the environment. A special government body "has a decisive say" in all matters touching on potential hazards "as early as the planning stage", deciding on the siting of the plant and the anti-pollution measures and equipment to be used. The main problem, he said, is that of existing plants which do not meet the more stringent modern requirements; Bulgarian industry is developing very rapidly and, accordingly, "everything has to be brought up to standard as soon as possible".

His own ministry, said Mr Tsvetanov, was particularly concerned with the purification of gaseous and liquid effluent. There is a "very substantial investment" in anti-pollution equipment, he added, "approximately 5%" of all capital invested in industry. He stressed, moreover, that his ministry's work is only part of an over-all plan for environmental protection.

Asked whether Bulgaria had made any major innovations in conservation and anti-pollution measures, Mr Tsvetanov said that it was "very difficult to say" if Bulgaria had achieved any major breakthrough.

This was a surprisingly modest remark in view of the numerous successes announced in the Bulgarian media. During the past month, Bulgarian radio has described new closed-cycle effluent-free production processes for copper, zinc, lead and molybdenum developed by the Bulgarian Academy of Sciences, a "superior" new coagulant for use in water purification, likewise from the academy, and an "efficient" method of recovering mercury from effluent, developed by the Sofia Institute of Chemical Engineering.

Vera Rich

Tamarugo, a high-protein leguminous plant which survives Chile's Atacama desert. Research on species such as this could bring great benefits.

"A goldmine" for scientists in third world

"THE vast majority of agricultural research has been on north temperate species in north temperate research stations. This research has been done by the countries that need it least." Yet, 85% of all plant species grow in the tropics. This is "a goldmine of new material waiting to be worked", declared Arthur Bell, Botany Professor at King's College, London.

He was speaking in London Saturday at a symposium on "What kind of science for African Development?". The meeting is intended to be the first of a series run by the UK African Studies Association.

Bell also argued that research has concentrated on cereals, because they are more important in north temperate zones, whereas legumes are more important for developing countries, which are usually tropical. Legumes fix their own nitrogen, reducing the demand for chemical fertilisers, they are rich in protein, and they grow in the most inhospitable places.

Of the 17,000 species of legumes, most grow in the tropics. But few kinds of legumes are eaten, because most are toxic to man. Some have been bred over the centuries: lima or butter beans now contain less than 3% of the cyanide of their natural Javan ancestor.

He suggested that research should concentrate on already existing minor crop plants to make them more acceptable. "One can improve a plant in its own habitat with many fewer gene changes than by bringing a plant from far away in Rothamsted", UK experimental station.

One example, based on his own research, is the *Lathyrus* of which most species are toxic. (The common sweet pea is a *Lathyrus*). In India, various *Lathyrus* species are commonly used

for food, but if eaten in large amounts cause a paralysis of the legs known as Lathyrism. Researchers found that the toxin was oxalyl-L-lysine. Bell showed that it was easy to use high voltage electrophoresis to test for this acid, and that not all *Lathyrus* species contained it. In a paper in *Nature* more than 15 years ago, he suggested that India substitute non-toxic *Lathyrus* species.

He now admits that this was a naïve suggestion. The three commonly eaten toxic species grow well and were rich in protein. But a variation of his suggestion was adopted. Indian agricultural scientists used high voltage electrophoresis to find that there was great variation in the toxin within the species, and are now substituting less toxic varieties. Similar work has been done in Australia to make *Leucaena* less toxic to animals.

Bell's concern about the research bias toward the developed countries was picked up by other speakers. Indeed, the conference convener Paul Richards noted that although Bell's work was of direct use of developing countries, it was done in London rather than a developing country.

Barbara Harriss of the University of East Anglia, in a paper on the Sahel submitted to the symposium, pointed out that research funded by Western agencies tended to support particular policy aims. For example, the World Bank was looking for technological packages that the first world could export to the third. And aid donors tended to support government marketing and agricultural structures. Yet as a rule neither of these help the poorest peasants. Indeed, research has ignored what the peasants actually eat—their nutrition and preferences and what factors affect their food consumption.

Joseph Hanlon

Joseph Hanlon is a development journalist specialising in third world science.

news in brief

Japanese physicist in UK fights deportation:

Dr Tetz Yoshimura is neither a political refugee nor a victim of economic or racial pressures—simply a mathematical physicist who wishes to pursue his researches unhampered by the materialistic rat-race of modern society. For this reason he left his native Japan in 1963, and, after holding a number of academic appointments in various countries came to the UK in 1971. Britain, however, is now proving a reluctant host, and Dr Yoshimura is fighting a deportation order.

After two years as a research fellow at the University of Essex and Kings College, London, Dr Yoshimura adopted a freelance life, concentrating on his research and supporting himself by freelance translation and the like. By drastically paring down expenditure on creature comforts, he claims that he can maintain himself on £12 per week, and that his average income is usually comfortably double this sum.

The Home Office, however, demand proof of a regular £100 per month before they will give him the papers necessary for permanent residence. Furthermore, since his original entry permit described him as a "student", his original application for permanent residence was rejected, apparently as a matter of routine.

Dr Yoshimura is an active researcher in axiomatic quantum field theory with papers published in 1978-79 in the *Physical Review*, *Journal of Mathematical Physics* and *Physics Letters*. This line of work is hardly one to engage the interest of the average civil servant. Nor, indeed, is his spartan lifestyle. Lord Avebury, the Liberal spokesman on immigrant problems, who is greatly interested in Dr Yoshimura's case told *Nature*: "The Home Office want everyone to fit into their procrustean rules. If you have rigid rules, there will always be cases where for reasons of humanity and common-sense, exceptions ought to be made. Dr Yoshimura's case is an example of this!"

US asked to reduce occupational radiation levels on basis of study of British dock-yard workers: A Washington lobby group has asked President Carter to implement a ten-fold reduction in the permissible exposure to radiation of US workers on the basis of a British study of nuclear dock workers which has demonstrated that low level radiation can result in a significant increase in chromosomal damage (*Nature*, 15 February, p. 531).

In the letter, Dr Sidney Wolfe and Alexander Harris of the Health Research Group claim that almost five thousand workers in US atomic power plants were exposed to the levels of radiation that, in the British study, induced a four-fold increase in the incidence of damaged chromosomes over a ten-year period.

According to the group, the total radiation exposure in US atomic power plants increased 23% between 1976 and 1977, while the number of operating plants increased by only 8%, from 39% to 42%. Furthermore the number of workers exposed to more than 0.5 rem increased by 25% over this period to a total of 16,712. This is the level to which permitted exposure levels have been suggested should be reduced by Dr Edward Radford, chairman of the National Academy of Sciences committee on the Biological Effects of Ionising Radiation, whose own report is to be published within the next few weeks.

● The Nuclear Regulatory Commission last week ordered the temporary shutdown of five East Coast nuclear power plants following evidence that a "simple arithmetical error" in a computer formula may have resulted in cooling system pipes being made six times too weak to withstand the effects of an earthquake.

GMAG notice on self-cloning will exempt certain experiments:

Following a meeting on March 16, GMAG are expected to release a statement within the next two weeks on their requirement for notification of so-called 'self-cloning' experiments. Unsurprisingly, they have apparently decided to 'exempt' experiments in which genes from *Escherichia coli* are cloned in *E. coli*, genes from *Bacillus subtilis* in *B. subtilis*, and yeast genes in yeast. Those wishing to carry out such experiments will still be required to inform GMAG of their intention and will be expected to carry them out under conditions of 'good microbiological practice'. Also under consideration are proposals to handle in a similar way work with certain rigorously characterised recombinant DNA clones that have been agreed to carry no possible hazard.

MRC taken to High Court: A further action has been started by solicitors for Dr Amiram Ur (21/28 December 1978) against the Medical Research Council. In addition to proceedings before the industrial tribunal for unfair dismissal a High Court writ served last week claims damages for breach of contract and wrongful dismissal, damages for losses due to negligence, breach of duty by the MRC in its conduct of Ur's application for tenured employment, and damages for "unlawful interference with the plaintiff's economic interests." The writ also names Professor I. M. Glynn of the Physiological Laboratory of Cambridge as co-defendant. Glynn was chairman of Ur's tenure committee.

Dr Amiram Ur's solicitors will now serve a statement of claim setting out in detail the allegations and the defendants will have to serve a defence. If the Court finds against the MRC damages could range from a payment of costs with a symbolic half penny award to the full amount claimed. Both the MRC and Professor Glynn had "no comment" to make on the action. Meanwhile the industrial tribunal reconvenes in London this week for another two weeks of hearings.

Geophysicists asked to write to Congress representatives to protect budget increases:

Members of the US geophysics community have been asked to spend six minutes working on letters to Congress representatives—urging them to support funds for basic science—for every hour spent preparing grant proposals, contracts and project justifications.

This suggestion of a commitment to "tithing" has been made by Professor Allan Cox, professor of geophysics at Stanford University and president of the American Geophysical Union. Writing in the union's newsletter, Professor Cox says that after several lean years of funding, the increase in funds for basic science promised by President Carter in his budget proposals for 1980 are necessary just to stay even.

"Moreover I would argue that to stay even we need to establish better communications with Congress", he says, pointing out that historically the basic research community—especially the academic part of it—has been "notoriously ineffective" in supporting its spokespersons in Washington. Such support is needed to protect the promised increases during the Congressional review process, he says.

According to Professor Cox, scientists are the only ones who can provide support for the administration's claim that their research is a good long-term national investment. "The pace of the budget process is such that a short letter now will be more useful than a long letter later."

Many members of the geophysics community were taken by surprise last year when Senator William Proxmire cut almost all funds for research into lunar samples brought back by the Apollo moon missions from the budget of the National Aeronautic and Space Administration.

US environmentalists provide some "good news" about energy: Adequate investment in energy saving techniques could allow the US economy to reduce its energy demand by 30-40%, and require only a 10-15% increase in energy usage over today's levels to maintain a healthy, expanding economy in the year 2000, according to a report published last week by the Council on Environmental Quality.

Techniques for increasing energy productivity include substituting heat pumps for electric resistance heating in homes, using greater insulation and more efficient appliances and machines in home and industry, and developing the use of total energy systems to generate heat and electricity simultaneously in commercial buildings, the report says.

"With a determined national effort to conserve energy, we can do well, indeed prosper, on much less energy than most people imagine," the chairman of CEQ, Mr Charles Warren, said on releasing the report, titled *"The Good News About Energy"*.

AAAS begins action against human rights violations in Argentina: The American Association for the Advancement of Science has decided to circulate widely its report and resolution on human rights violations in Argentina. The author of the report, Bruce Alan Kiernan, AAAS Human Rights Coordinator, observes that "Argentina continues systematically, in my view, to violate basic international standards of human rights: the right to security of person, to freedom from torture, to the right of trial and minimum standards of legal defense and appeal and humane standards of punishment". Of particular concern is the matter of disappeared persons, estimated by Kiernan to be between 20,000 and 30,000 people including many scientists—most of whom are believed dead. "40% of Argentine physicists have been kidnapped and some disciplines such as psychiatry no longer exist," says Kiernan. Senior advisors to President Videla admitted to Kiernan that many people in military custody were thrown out of helicopters, a tactic learned from American practice in Viet Nam. "I heard testimony of individual experiences in jails and detention centres and these accounts included descriptions of torture techniques that can only be described as horrendous." The AAAS resolution calls for scientific organisations to initiate on-site investigations in Argentina "on an urgent basis" and to release their results to their governments. The resolution also calls for the release and resettlement of falsely imprisoned Argentine scientists. The AAAS has asked the Human Rights Committee of the Organisation of American States to make a separate report on the condition of scientists. The AAAS Committee on Scientific Freedom and Responsibility regards the situation as "extremely bad" and has been meeting for the past week to consider among other things a call to scientists and scientific organisations to cut off all scientific exchanges to Argentina until the government restores human rights.

Friends of the Earth steps up campaign against Torness: The Torness Point nuclear reactor site in Scotland, the target for militant anti-nuclear demonstrations last year, is under new criticism from Friends of the Earth. On Wednesday, in what is described as "an eleventh hour effort to save us from yet another nuclear blunder" FOE

delivered a ten foot diameter millstone, the largest in Britain, to Bruce Millan, Secretary of State for Energy along with a copy of its report. FOE calls the government's outlay of £742m for Torness "an economic disaster twice the magnitude of Concorde". The report details numerous deficiencies in the government's proposal including: inadequate costing (a further £200-300m will be needed for the distribution system); inadequate need projections (the Scottish Electricity Board had a 65% surplus above maximum demand last winter); inadequate design on the two previous advanced gas cooled reactors; and loss of jobs (in the local community). *Torness: Keep it Green*. By Michael Flood. Friends of the Earth, 9 Poland Street, London W1V 3DG. 85p.

Shirley Williams proposes short term contracts for lecturers: In a speech on 5 March at The Times Higher Education Supplement's Conference on Trends in Education into the 1990s, Shirley Williams, Secretary of State for Education and Science suggested that short term contracts for university and polytechnic lecturers may become a necessity. Basing her argument on demographic considerations,

Williams predicted that a current "hump" in student enrolment would peak in the universities in the mid-1980s. Half the number of lecturers required to teach this excess above "background" could then be expected to be employed on short term appointments. In addition, Williams feels that short term contracts could provide room for young lecturers and for dismissal of older lecturers who had not fulfilled their "early promise". Laurie Sapper, General Secretary of the Association of University Teachers said that Williams' proposal was "just a disguised way of saying that the universities should employ cheap labour".

US report says no solution yet to nuclear waste disposal: An interagency working group has told President Carter that there is still insufficient evidence to assess the feasibility of safely disposing of nuclear waste in underground repositories, and that such evidence could only be acquired by investigating the suitability of particular sites.

The group, which was set up by President Carter last year, said that current knowledge was adequate only to identify possible storage sites for further investigations. It also said that conservative engineering judgment, as well as providing multiple barriers between radioactive material and the environment, could reduce some of the risks involved and compensate for some of the uncertainty.

West German fast breeder report criticised: Dr Ulrich Steger, chief spokesman of the SPD working group for research and technology in the *Bundestag*, has fiercely criticised a recent report on the future of the fast breeder in Germany. The report, by Dr August Eitz of the Schnell-Brüter-Kernkraftwerksgesellschaft (SBK), deplores the delay in licensing the prototype SNR-300 fast breeder at Kalkar on the Dutch-German border, minimises the risk of accidents, and argues that nuclear proliferation is unavoidable except by international surveillance. The use of nuclear energy leads logically to fast breeders to conserve uranium stocks, Eitz says. But according to Steger, Eitz—in order to put the breeder in a favourable light—has offered "only stale growth-fetishism". According to Steger anyone looking for the reasons why nuclear energy is in a difficult situation would find some of them in Eitz's speech.

INFCE looks for technical and institutional solutions

SIR,—I would like to make some corrections to the report entitled "INFCE halfway through" (8 March, page 112). Although the idea of INFCE was first suggested at the London Summit, it was set up in Washington in October 1977 and involves not only the Western industrialised nations but the Soviet Union, several of the East European States and quite a number of developing countries. It is incidentally organised into eight working groups, not twelve.

At the time INFCE started, the proliferation risks of reprocessing were indeed judged differently by on the one hand the United States and Canada and on the other all the major nuclear power users (not simply the UK as your article suggests). These countries all felt that the case for reprocessing must take into account environmental and economic factors; and that as spent fuel contained plutonium, spent fuel storage also carried proliferation risks. However, as a result of studies in INFCE it is now apparent that some intermediate fuel storage is necessary because it is most unlikely that world reprocessing capacity will be sufficient to deal with all spent fuel arising for perhaps another 20 years, and some spent fuel will therefore have to be stored for a considerable time.

Your article is correct in implying that there is no simple technical fix to the proliferation risks arising from the growing spread of civil nuclear power. But we are also engaged in an examination of institutional measures to counter the dangers of proliferation. The International Atomic Energy Agency has already shown itself to be an eminently valuable institution, especially its safeguards system, and it may well be that internationally controlled plutonium storage and internationally controlled spent fuel storage can be important further additions to world confidence.

Yours faithfully,

SIR HERMANN BONDI

Chief Scientist,
Department of Energy, London.

Defence R&D and SRC budgets are not comparable

SIR,—I was interested to see your editorial (1 March, page 1). Most members of the scientific community in the UK will agree with you that the "difficult question"—the minimum rate at which expenditure by the research councils should grow so as to sustain the health of research in the country—should be addressed with urgency. It is good to see a lead from the ABRC, for it is not only sustenance that is at stake; there is a vital need to repair the attritions of the past decade or more.

I regret, however, that you should have confused this important problem with a less than adequate examination of the relativities of government R&D resource allocation. The defence R&D budget and SRC expenditure set out to do quite different things: SRC remains, I believe, dedicated to the promotion of research of 'timeliness and promise', and the research councils accept responsibility—as they must—for the nurturing of the research function in universities, polytechnics and their own laboratories. Less than 1% of defence R&D expenditure can be identified with the support of innovative research: a matter of considerable concern to myself and my colleagues here. As the 1979 Defence White Paper—or the more recent Review of Cmnd 5046—indicates, more than 70% is invested in British industry (including, for instance, the important area of electronics) and is dedicated to the short term task of developing new equipment essential to the Armed Forces and national defence. Thus about 25% of the R&D budget finds its way to the defence establishments, and this too is overwhelmingly dedicated to short and medium term development work.

Moreover, I fear that your misunderstanding of the equivalence (or lack of it) between defence R&D and the SRC budgets reads over to your remarks on the competence of personnel in our R&D establishments. It will be clear from the above that the criteria for judging the ability and performance of scientists and engineers in defence laboratories must, in general, be quite different from those applied to my colleagues in the universities. This is not to say, of course, that MOD scientists inhabit a world isolated from the wider scientific community. We are always looking for ways of promoting contact; but communication is already frequent and fruitful, much of it through the Defence Scientific Advisory Council, which monitors very carefully the programmes of all R&D laboratories and which submits independent annual reports to the Secretary of State. There exist other forms of "peer review", internal and external, both for programmes and for individual scientists and engineers.

There may, in fact, be less complacency in defence about the need to repair the innovative function than there is elsewhere. The R&D establishments have suffered considerable erosion for a number of years, during which their work has been directed away from the long term innovative task. It would be unfair to attack them now on the basis of a spurious comparison of their contribution to microbiology or solid state physics, or whatever, with those emerging from research sponsored by the research councils. The latter are conducted for different purposes, and are different in kind.

Yours faithfully,

RONALD MASON

Chief Scientific Adviser,
Ministry of Defence, London.

Pitldown stains

SIR,—In your correspondence columns (22 February, page 596) Dr L. B. Halstead recalls that he refuted my suggestion (*The Times*, 7 November 1978) that Sollas may have used potassium bichromate to harden fossils to which he applied his serial sectioning technique. I wrote a letter in reply, but it was not published owing to the temporary cessation of *The Times*. I accept the validity of the evidence which Halstead found in the records of the University Museum, Oxford, showing that all the fossils to which Sollas applied serial sectioning were hard by nature, and therefore required no artificial hardening. The truth of the matter is that after the passage of some 70 years there is nothing to be gained by speculating on the purpose for which Sollas ordered the packet of bichromate crystals. As I pointed out in my letter to *The Times* of 7 November, Charles Dawson himself stated that he soaked some of the Pitldown bones in a solution of potassium bichromate, allegedly for the purpose of hardening them. Only by special pleading could anyone argue that this chemical was ordered by Sollas for delivery to him in Oxford, after which (one would have to suppose) it was forwarded to Dawson in Lewes with instructions as to how it might be used. These are the thoughts of a Jabberwocky! Dawson would have had no difficulty in obtaining potassium bichromate from a pharmacy in Sussex.

Researches by Dr (now Sir Frank) Claringbull and Dr M. H. Hey at the British Museum (Natural History) (Further Contributions to the Solution of the Pitldown Problem, *Bulletin of the British Museum (Nat. Hist.)*, Geology series, vol 2, no 6 (1955)) showed that the Pitldown cranial bones had been artificially stained by treatment with a solution of an iron sulphate. The additional use of a bichromate solution can now be understood because it would serve to aid the oxidation of a ferrous iron salt and thus the production of rusty staining. So the bones, which were originally of pale biscuit colour, in the end matched the dark reddish-brown Pitldown gravel in which they were supposed to have been found.

Dawson is known to have carried out experiments on the staining of bones and flints. He may well have required advice from somebody with greater knowledge of chemistry than he himself possessed, but it is unlikely that he would have sought help from the Oxford Professor of Geology. He was in a position to obtain chemical advice locally: in his first paper on Pitldown, read to the Geological Society in December 1912, Dawson thanks Mr S. A. Woodhead, Public Analyst of East Sussex, for chemically testing a piece of the Pitldown cranium and reporting that no organic matter could be detected in it (recent analyses of the cranial bones showed protein residues represented by 0.2–1.9% nitrogen).

Yours faithfully,

KENNETH P. OAKLEY

Aetiology and genetic control of natural scrapie

from Richard H. Kimberlin

SCRAPIE disease, a neurological disease found naturally in sheep, is generally considered to be caused by a transmissible agent. Recently, however, Parry¹, on the basis of studies of the incidence of natural scrapie in commercial flocks has reiterated his long-held belief^{2,3} that scrapie is a disease solely of genetic origin, controlled by an autosomal recessive gene. Although Parry does not dispute the existence of a transmissible scrapie agent he believes it to be "formed *de novo* in each affected animal by the metabolic activity of the natural recessive gene", and considers it irrelevant to the disease, or at least not involved in its spread.

In view of his comments it may be useful to re-examine the role of the transmissible agent in scrapie. Many scientists in the field consider that scrapie is caused by a transmissible agent, with host genetic factors exerting some kind of control on the development of clinical disease. In my opinion this interpretation is not only supported strongly by available data but it does not conflict in any way with Parry's interesting results.

Evidence for a transmissible agent

There is no doubt that the injection of brain homogenates from affected sheep will transmit the disease to other sheep after long incubation periods⁴. The transmissible agent can be filtered^{5,6} and experimentally passaged in sheep to extremely high dilutions of original inoculum⁷, thus showing the presence of a replicating, virus-like agent. Experimental forms of scrapie have been produced in many species⁸, mice in particular, and it is notable that mouse-passaged agent can also be injected into sheep to produce scrapie^{9,10}. This evidence alone provides a substantial reason for concluding that the transmissible agent causes the natural disease.

Many different strains of scrapie agent have been isolated in mice from natural sources⁴ and it is now known that some of these strains undergo mutation on serial passage¹¹. Strain

variation and mutation are the expected attributes of a pathogenic microbial agent. There is a serious problem with Parry's suggestion "that the scrapie TSEPA [transmissible spongiform encephalopathic agent] is formed *de novo* in each affected animal by the metabolic activity of the natural recessive gene" because one has to explain how a single host gene can produce biologically different strains of agent, sometimes in the same animal⁴.

However, the main issue raised by Parry is not the existence of the scrapie agent but whether or not it is naturally infectious. I would like to summarise three major studies that strongly indicate natural spread of agent from one animal to another.

In one experiment¹², 11 Blackface sheep were close-penned from birth until 3 to 4 years of age with a succession of naturally affected sheep. Four died of intercurrent disease before they reached an age at which scrapie first occurs, but three of the remaining seven developed scrapie. In the same study¹², 17 goats were exposed under similar conditions and 10 of these developed scrapie. As considerable care was taken to ensure that the exposed animals were obtained from scrapie-free stock the high proportion of scrapie cases in Blackface

sheep (43%) and in goats (59%) strongly suggests contagious spread.

In a second experiment¹³, the exposed Scottish Blackface sheep came from a well documented flock in which no cases of scrapie had been seen in over 18,000 sheep during 13 years. However, when some of these Blackface sheep were kept in life long contact with a Suffolk flock with a high incidence of natural scrapie, and managed under normal commercial conditions, 21 (28%) of the exposed sheep developed scrapie. It is extremely difficult to explain such a high level of scrapie in the Blackface sheep except by contact spread of agent.

Even more impressive data have been obtained from the USA with Angora, Nubian and Toggenburg goats and Rambouillet, Targhee, Hampshire and Suffolk sheep, all from scrapie-free flocks. It should be noted that no field cases of scrapie have been found in Angora goats or in Rambouillet or Targhee sheep in the USA. Yet when these and the other animals (total 140) were put in contact with scrapie-affected flocks, five developed the disease¹⁴. These 140 animals were bred within their own groups in the scrapie environment and produced 358 progeny that survived for at least two years. Of these, 9% (27%) developed scrapie. The figures for individual

breeds ranged from 14 to 39% for sheep and from 26 to 61% in goats¹⁴. Again, the conclusion that contact spread of scrapie occurred seems inescapable.

Genetic control

The evidence that scrapie is an infectious disease is clearly incompatible with a disease of genetic origin. However there is no reason why genetic factors in the host should not control the process of infection or the development of disease once infection has taken place and this was the conclusion drawn from other studies of genetic factors in natural scrapie^{4,13}.

There are three major studies showing that the probability of a lamb's developing scrapie depends more on the eventual scrapie status of the ewe than of the ram¹³⁻¹⁵. These observations of maternal bias indicate transmission of infectious agent from ewe to lamb and there is evidence from other sources that agent is probably passed to the embryo^{4,16,17}. However the extent of this maternal bias will depend on many factors, not least of which is the level of contagious spread of agent, which if relatively high may obscure maternal transmission. Hence the fact that Parry finds no evidence for maternal transmission of agent may simply mean that in some situations it is not of paramount importance.

The only other area where there are conflicting data concerns the nature of the genetic control exerted by the host on the development of disease. Parry's results¹ indicate that the natural disease in his flocks is controlled by an autosomal recessive gene whereas another study¹³ showed a more complex and unresolved genetic control of natural scrapie. Two further investigations^{18,19} demonstrated that the development of clinical scrapie in Cheviot and Herdwick sheep following injection with the SSBP/1 source of scrapie agent was mainly controlled by a single gene with the fully dominant allele conferring susceptibility. A broadly similar genetic control of the natural disease in these two flocks is indicated by the subsequent appearance of natural scrapie which is largely confined to the susceptible lines^{4,20}. This diversity of findings cannot easily be explained at the moment but the following observations may be relevant.

First, given that scrapie is caused by an infectious agent, then variables such as the strain of agent, the relative importance of maternal and contagious spread of infection and the age of the animal when exposed, could conceivably involve different genetic components.

Second, the genetic studies of experimental scrapie in Cheviot¹⁸ and Herdwick¹⁹ sheep used the same source

of scrapie agent and gave similar results. However it has now been shown that the response of genetically selected lines of Cheviot sheep to an agent designated CH1641 is quite different from that found with SSBP/1 (refs 4,10). This means that the genetic control of experimental sheep scrapie varies with the strain of agent.

The third point follows from this and concerns the interaction seen between different strains of mouse-passaged scrapie agent and the murine gene *sinc* which controls incubation period^{21,22}. The gene has two alleles, *s7* and *p7*. Many agent strains (for example) ME7, 22C, 139A) have a shorter incubation time in mice homozygous for *sinc*^{s7} than in *sinc*^{p7} mice, but agents such as 22A have the reverse properties. When comparisons are made of incubation periods in *s7p7* mice, the interactions between agents and the alleles of the *sinc* gene range from no dominance or partial dominance of one or other allele, to full dominance and even positive overdominance in which the incubation period is longer in the heterozygote than in either of the homozygotes^{21,22}.

If this level of complexity applies to the natural disease then it would be quite wrong to expect the genetic control of scrapie to be the same in all situations and the fact that different studies have given different results may be a reflection of this. □

Richard H. Kimberlin is Scrapie Project Leader, ARC Institute for Research on Animal Diseases, Compton.

Conversion of mouse fibroblasts into adipocytes

from Franklin H. Portugal

AN important new avenue of research on lipid metabolism and obesity has been opened up through the conversion of mouse fibroblasts into adipocytes under defined culture conditions. In 1974, Green and Kehinde (*Cell* **1**, 113; 1974) observed a few cells with lipid droplets in resting cultures of 3T3 mouse fibroblasts. They suggested that these observations indicated the establishment of clonal lines of fibroblasts that have a high frequency of conversion into adipocytes when their growth is arrested. Because low concentrations of bromodeoxyuridine block this conversion without affecting other specialised cell functions such as collagen synthesis, the conversion process

involves differentiation of the fibroblast.

In contrast to the fibroblast, the adipocyte acquires the signet ring appearance of adipose cells, accumulates triglycerides, and loses the ability to revert to the growing state. Insulin, L-adrenaline, N⁶, O^{2'}-dibutyryl cyclic AMP and isoproterenol alter the incorporation of precursors into triglycerides in the adipocytes. During the conversion from fibroblast to adipocyte, there is a 40-50-fold increase in the incorporation of ¹⁴C-acetate into triglycerides. This increase is paralleled by an increase in lipogenic enzyme activities including acetyl-CoA carboxylase, ATP-citrate lyase, and fatty acid synthetase (Mackall *et al. J. biol. Chem.* **251**, 6462; 1976). For one of these enzymes, acetyl-CoA carboxylase, the increase in activity is due to an increase in the cell enzyme level as determined by measuring the change in immunotitratable enzyme. Lipoprotein lipase, a lipolytic enzyme, also increases rapidly during the post-confluent period (Eckel *et al. Biochem. biophys. Res. Commun.* **79**, 720; 1977). The conversion of 3T3 fibroblasts to adipocytes is also sensitive to agents that affect cyclic nucleotide levels, such as prostaglandin F₂ and 1-methyl-3-isobutyl xanthine (Russell & Ho *Proc. natn. Acad. Sci. U.S.A.* **73**, 4516; 1976). Adenylate cyclase of adipocytes compared with the enzyme in preadipocytes is markedly stimulated by isoproterenol and shows a response to adrenocorticotrophic hormone (Rubin *et al. J. biol. Chem.* **252**, 3554; 1977). Near-physiological levels of insulin stimulate the conversion of glucose into carbon dioxide and lipid only in the adipocyte.

Serum factors also seem to play a part in the conversion of fibroblasts. Recently, Kuri-Harcuch *et al. (Cell* **14**, 53; 1978) reported that in serum-supplemented medium, 3T3 fibroblasts can still apparently differentiate into adipocytes even in the absence of biotin which is essential for fatty acid synthesis. They became spherical, the activity of NAD-linked glycerolphosphate dehydrogenase increased 300-fold and the activity of lipoprotein lipase increased 50-fold. But without biotin the cells were unable to increase the rate of acetate incorporation into triglycerides.

Subsequently Kuri-Harcuch and Green (*Proc. natn. Acad. Sci. U.S.A.* **75**, 6107; 1978) have identified a non-lipid adipogenic factor in serum. In the presence of this factor, cells grown to confluence become spherical, increase their malic enzyme and glycerolphosphate acyltransferase activities, and accumulate triglycerides, whereas in its absence none of this occurs. Fetal calf serum is much richer in this factor than calf serum or the other

Franklin H. Portugal is a science writer at present working on a history of the Carnegie Institution of Washington.

mammalian sera that were tested. This serum factor differs from biotin in that it regulates cell shape and differentiation of cell enzymes.

Négrei *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **75**, 6054; 1978) now report that they have established a clonal line of adipose cells from epididymal fat pad cells of genetically obese C57BL/6J *ob/ob* mice. At the resting stage, these converted fibroblasts accumulate triglycerides. Differentiation of these cells is accompanied by increased lipoprotein lipase, acid:CoA ligase, and acyl-CoA:diglyceride acyltransferase activity. They respond to hormones including adrenaline, corticotropin, and insulin. Bromodeoxyuridine almost totally prevents the presumed induction of the triglyceride-pathway enzymes. Conversion of *ob* 17 cells to adipocytes apparently differs in several respects from the conversion of 3T3 cells obtained from the Swiss mouse embryo. These differences may include sensitivity to insulin and biotin as well as lower values for fatty acid biosynthesis.

The fact that these adipocyte cells in culture show many of the same characteristics as adipocytes *in vivo* suggests that they can be useful models

for understanding the factors that control obesity. Comparisons of adipocytes from genetically and non-genetically obese mice may help to clarify the genetic factors that regulate obesity. Furthermore, studies of lipid metabolism that are difficult with intact animals are now simplified. For example, the use of adipocytes in culture suggests that the appearance of lipoprotein lipase is not substrate-induced by the presence of serum triglycerides or lipoproteins. These cells are also important for distinguishing true lipogenic enzymes such as pyruvate carboxylase from lipogenic-type enzymes such as aldolase. An understanding of how fibroblasts are converted into adipocytes should also increase our understanding of the mechanisms that control cell differentiation. In addition, these cells can increase their number of insulin receptors whereas most systems show either no change in response to increased insulin levels or decrease their number of insulin receptors. Thus, the conversion of fibroblasts into adipocytes will also be useful for determining the factors controlling receptor development. □

mean atomic weight is effectively constant to within 2%, and Shankland (*Geophys. Surv.* **3**, 69; 1977) has suggested on the basis of a study of chemical and crystallographic properties of supposed mantle materials that "the mantle appears to be chemically homogeneous". Above 700 km the mean atomic weight is apparently more variable because of the occurrence of phase transitions at several depths; but Schubert and Turcotte (*J. geophys. Res.* **76**, 1424; 1971) have already shown that convection is not thereby prohibited. In summary, then, there appears to be no significant reason why convection should not occur anywhere in the mantle.

The case for whole-mantle convection as such was recently boosted by the detailed studies of Davies (*Geophys. J.* **49**, 459; 1977) who used the arguments quoted above, among others. And it has now been given further support by Elsasser *et al.* (*J. geophys. Res.* **84**, 147; 1979) who have set the scene for the decision that must ultimately be made between, on the one hand, convection down to 700 km only, and, on the other, convection down to the core-mantle interface. As Elsasser and his colleagues point out, the "entire question of mantle convection has lately entered a new stage" in view of the conclusion by Rochester *et al.* (*Geophys. J.* **43**, 561; 1975) that precession provides too little power to drive the core dynamo, which must therefore be driven either by radioactivity-induced thermal convection or by the progressive falling out of Fe and Ni at the boundary of the inner core.

It follows from this (cutting out many stages of the argument) that, if radioactive heat transfer in the mantle is small (as is widely supposed), there must be a hot thermal boundary layer at the base of the mantle, for the quantity of heat leaving the core will be greater than the mantle can dissipate by conduction alone. The build-up of heat that this implies will then result in the detaching and upward motion of parts of the boundary layer material, thereby setting up a system of motion in the mantle. From this starting point, and the deduction that the temperature at the core-mantle interface is $4,000 \pm 500$ K, Elsasser *et al.* go on to develop a model of whole-mantle convection that works in the sense that, for all its assumptions, it is consistent with global heat flow, plate sizes, plate speeds, mantle viscosity and certain seismic data.

The picture thus conjured up is one of extreme simplicity—whole-mantle convection moves continents and sea floors and leads to surface volcanism whilst whole-(outer)core convection generates the lower boundary condi-

Mantle convection: shallow or deep?

from Peter J. Smith

A QUESTION that has exercised the minds of geophysicists on and off for more than 40 years now, is that of the vertical scale of convection in the mantle, assuming that convection takes place there at all. Thoughts on this subject may be divided conveniently into three periods. During phase 1 the pioneers (Vening, Meinesz, Holmes, Runcorn for example) evidently took it for granted that convection would be mantle deep, a view that prevailed generally (at least among the supporters of continental drift) up to the early 1960s. But the rapidly growing appreciation of the special properties of the asthenosphere—in particular its relatively low viscosity—gradually convinced many, but not all, that convection limited to the upper mantle was a viable alternative. Not that convection was regarded as necessarily being limited to the asthenosphere itself—that is, to a maximum depth of about 250 km. Some took the view that 700 km or so should be regarded as a lower limit because earthquakes occur to that depth, largely in subduction zones where lithosphere is descending. Either way, however, it

did not seem unreasonable to suppose that convection stopped well short of the core-mantle boundary at 2,900 km. That was phase 2.

Phase 3 began sometime during the past two or three years, marking a period of maturity during which both shallow and deep convection hypotheses must battle it out on more equal terms.

For example, by the late 1960s a number of geophysicists had concluded that below the asthenosphere the viscosity increases rapidly with depth in the mantle, thereby, it was suggested, making convection in the deeper mantle impossible. But ideas on that have now changed, largely as the result of the work of Cathles (*The Viscosity of the Earth's Mantle*, Princeton University Press, 1975) and Peltier (*Geophys. J.* **46**, 669; 1976) who have made convincing cases (by different routes) for a mantle viscosity more or less constant at about 10^{22} poises below the asthenosphere.

Another condition that would preclude whole-mantle convection would be a variation of gross chemical composition with depth. But Watt *et al.* (*Geology* **3**, 91; 1975) have concluded from free oscillation data that between 700 km and 2,900 km in the mantle the

Peter J. Smith is a Reader in the Department of Earth Sciences at the Open University.

tions for mantle convection as well as the geomagnetic field. Moreover, as volcanism has evidently been occurring and the geomagnetic field has evidently existed for at least 3×10^9 years and probably getting on for 4×10^9 years, the convective systems would appear to be almost as old as the Earth. As Elsasser and his coworkers concede, "this is in line with Tozer's often expressed view that since planets are convectively unstable and since the radioactive heat of their interiors can only be removed by convection (for example, Tozer *Phys. Earth Planet. Int.* 6, 182: 1972), most planets can be expected to convect most of the time".

Obviously an excellent case can be made for whole-mantle convection. Whether it actually occurs or not is more difficult to prove. □

Reproduction in flowering plants

from A. J. Richards

INTRODUCING the International Symposium on the Reproduction of Flowering Plants, held recently in New Zealand*, E. J. Godley (DSIR, Christchurch) discussed the special characteristics of the New Zealand flora. One question posed was whether the proportion of unisexual flowers found in New Zealand is as uncommon as has been previously supposed. Twelve per cent of the 1,800 species of indigenous flowering plants are dioecious (with stamens and pistils on different plants) compared with 2% of indigenous UK species. However, high frequencies of unisexual plants are common in tropical forests (as shown in Costa Rica recently by K. S. Bawa (University of Massachusetts)) and are found in all temperate countries south of the Equator. Dioecy is generally regarded as being a secondary phenomenon, hermaphrodite flowers being the primitive type in the flowering plants, so it seems unlikely that dioecy is a hang-over from the ancient southern continent of Gondwanaland. Perhaps the high level of variability and vigour engendered in outbreeders was favoured during the establishment phases of the southern land-masses, as they became increasingly isolated from the mainstream of flowering plant evolution to the north.

Godley also discussed the predominance of white and yellow flowers in

New Zealand, so well-known in the hebes, olearias and celmisias cultivated in the UK. He quoted Cockayne, stating that of attractive flowers, over 60% are predominantly white flowered in New Zealand (the comparable figure for the UK is 25%). Certainly, the experience of a casual visitor from Europe, faced with white gentians, white buttercups, white willowherbs and white forget-me-nots bears this out. Godley thinks that white flowers, mostly of an unspecialised nature, might also be representative of an ancient, isolated southern continent, and many anthecologists would agree that this simple syndrome ties in well with the paucity of pollinators that a land-mass, isolated so early, might be expected to demonstrate. Specialisation of flowers will only succeed if a rich flower-visiting fauna is present.

Until recently, gynodioecy, in which pistillate and hermaphrodite plants are mixed, was thought to be uncommon. A number of workers showed that it is much more frequent than previously realised. Theoretically, it is difficult to model a balanced gynodioecy; either the disadvantage to pistillate flowers of requiring cross-pollination for seed to set, and having fewer potential pollen sources; or the advantage of not bearing the reproductive cost of stamens, is likely to upset the balance. This is compounded by the tendency for male sterile genes to be carried cytoplasmically, and thus to be inherited maternally. It was suggested that in stable gynodioecious conditions, nuclear-controlled male fertility restorers help natural selection in the maintenance of a balance between male fertile and male sterile plants. Marianne Philipp (University of Copenhagen) provided some interesting data to show how this balance might operate selectively.

X. Delanny (University of Louvain) echoed the work of other speakers in showing just how cryptic gynodioecy can be. Most European species of thistle are gynodioecious, but the over-familiar creeping thistle, *Cirsium arvense*, is usually fully dioecious although morphologically the flowers appear hermaphrodite. Females show early abortion of pollen, despite normal looking anthers, and males have perfectly functional pistils, apart from the pollen-receptive papillae on the stigma, which fail to develop.

As in so many other sciences, reproductive genetics seems to be emerging with difficulty from a model-building phase, and there are still more ideas than facts. However, this is much less true with respect to recent work on the physiology of sexual fusion in flowering plants. Using technically outstanding light and electron micrographs

of cotton ovules W. A. Jensen (University of California, Berkeley) has followed the fate of the male gamete immediately before fertilisation in fascinating detail. The generative nucleus of the pollen tube is a true cell, surrounded by a plasma membrane. On entering the embryo-sac, the pollen tube forms an association with one of the synergid nuclei. This synergid grows and migrates to the egg nucleus, carrying the male cell which has been discharged by the tube into the synergid. Plasma membrane between the male cell and the egg are sequentially broken down, finally permitting controlled fusion. The remains of the synergid subsequently throws out the second male nucleus towards the fused polar nucleus (with which it will fuse to form the triploid endosperm). The polar dikaryon has already fused on the stimulus of pollination, and this fusion is probably triggered by secondarily produced gibberellic acids. In a similar way, the growth and change of appearance of the receptive synergid is apparently triggered hormonally, and can be induced by auxin placed on the stigma in the absence of pollen. There is now good evidence that the directional chemotaxis of the pollen tube occurs in response to a calcium gradient, according to evidence achieved with the use of ion-analysing microprobes.

Ultrastructural work has also thrown light on the control of apospory, a form of agamospermy (seeds without sex) in the New Zealand grass *Cor-dateria*. Melva Philipson (DSIR, Christchurch), showed that sexual meiosis is able to proceed towards the formation of megaspores and an embryo-sac, protected by a callose sheath. In aposporous conditions, the callose breaks down early, and the megaspore mother cell degenerates, allowing the formation of vegetatively budded, maternal embryo-sacs, which develop embryos autonomously, identical to the parent.

There was much more to report at this conference: a mass of exciting anthecological and breeding system work is emerging from the botanical wealth of Australia, which with over 20,000 species of flowering plants, and a host more waiting to be described, bids fair to replace California as the evolutionary field laboratory of the world. Exciting new techniques were also in evidence, especially in the fields of cell fusion studies, somatic gene transmission, embryology, using new clearing techniques to replace tedious sectioning, and the use of artificial dried 'seeds' cloned from tissue cultures. □

Snipe-eels unravelled

from a Correspondent

THE snipe-eels are a family of eels found in mid-water in deep sea throughout all the temperate and tropical oceans. They derive their common name from the extraordinary elongation of the jaws which resemble a snipe's bill, except that the tips curve outwards in the vertical plane. In common with almost all groups of eels there has been much confusion in the nomenclature and systematic arrangement of the group although for several reasons the snipe-eels have been exceptionally complicated. A recent study by J. G. Nielsen and D. G. Smith on the eel family Nemichthyidae (*Dana-Report* No. 88, 1; 1978) will, however, go a long way to clearing up the confusion in these fishes.

One of the problems with these eels is that they live in mid-water and until the development of effective mid-water nets in the middle of the present century, most of the specimens seen by naturalists were accidental captures made while hauling bottom trawls. Indeed, it is not infrequent for deep-water fishermen to find snipe-eels entangled by their slender 'beaks' in the wings of a bottom trawl. Most of the specimens described by early ichthyologists were thus isolated captures and often not in good condition (*Nemichthys scolopaceus* grows up to 1 m in length, is about 2 cm deep at its deepest part, and less than 1 cm wide—so general fragility might be expected). Another potent source of confusion arose from this fragility, such as when one species was described as new to science on the grounds that there was a ridge of skin on the dorsal surface of the snout—a feature which Nielsen and Smith show to be due to shrinkage of the skin. These and other factors all lead to a thorough con-

fusion within the family, and it seems from the historical account of Nielsen and Smith that the group was fated to attract workers who failed to appreciate critical differences and even similarities. Since 1848, when the first genus *Nemichthys* was described, no fewer than eleven other genera have been proposed in the family, and the plurality of species has been even greater. In the current revision this has been reduced to three genera; only nine species are recognised.

A major factor in the artificial boost in the number of species was that mature male snipe-eels look totally dissimilar to females and immature fish. This sexual dimorphism was demonstrated by Smith and Nielsen (*Steenstrupia* 4 (1), 1; 1976) in a preliminary note, but the phenomenon is discussed in greater detail in their current revision. At sexual maturity male snipe-eels lose the characteristic snipe-bill, lose their teeth in the process, develop tubular anterior nostrils, change colour, and their pectoral fins move posteriorwards. Sexually mature females may also change colour and partially lose their teeth. So great are the differences between males and females that for over 50 years they have been placed in separate genera, and by some workers even in separate families and suborders!

It seems probable that the males at least spawn once and die soon after. The scarcity of short-nosed snipe-eels in collections suggests that they are rare in nature. However, as Nielsen and Smith point out, fishing gear may select in favour of the females, which having teeth and long snouts are more likely to become tangled in netting than are the toothless, short-snouted males. No doubt their study will stimulate further investigation of the ratio of male to female snipe-eels.

The fascinating shape of the jaws is briefly discussed but no new light is

shed on the means by which these fish capture their food, which is mainly crustacean. An earlier suggestion by G. W. Mead and S. A. Earle (*Proc. Calif. Acad. Sci.* 38 (5), 99; 1970) was that the long, tooth-studded non-occlusible jaws might be used to entangle the antennae of the sergested and hoplophorid shrimps which they eat. The backward-pointing teeth would ensure that any trapped animal could only move towards the gullet, and yet the awkward divergence of the upper and lower jaws hardly seems to be an efficient method of capturing food.

Nielsen and Smith's study is a major advance in clarifying the confusion in taxonomy of the snipe-eels, but it is unfortunate that it appeared at almost the same time as the publication of a study by E. S. Karmovskaya (*Trudy Inst. Okeanol.* 109, 186-210; 1977) on the taxonomy and distribution of the genus *Borodinula*, with the description of a new species. Nielsen and Smith refer to this paper in a postscript added in proof, pointing out that Karmovskaya's new species is a species they consider was described as long ago as 1916, while *Borodinula* is a synonym of *Avocetina*. Evidently the era of confusion in snipe-eels is not yet over.

Equatorial upwelling rates

from M. Tomczak Jr.

ESTIMATES of vertical velocities in the ocean have long been a matter of interest in oceanic science since the supply of nutrients for the surface layer where primary production through photosynthesis can take place, almost exclusively depends on renewal from below. Apart from the important coastal upwelling regions along the coasts of California, Peru, North-west and South-west Africa, there is clear evidence for strong upwelling caused by a divergence in the surface layer flow along the Equator. To estimate the productivity of the region, however, is difficult because upwelling rates, that is, the amount of water which upwells into the surface layer per unit time interval cannot at present be measured directly. Average vertical velocities are believed to be of the order of a few centimetres per day or less.

Theoretical estimates of upwelling rates are usually based on the calculation of 'Ekman layer suction', the amount of water absorbed into the surface layer from below in order to compensate for local losses due to divergences in the surface currents. Since surface currents are wind-driven it is possible to calculate this effect

Fig. 1 Radiocarbon content of the Atlantic Ocean, integrated over the water column. The dashed lines define the equatorial and temperate zones in the study of Broecker, Peng and Stuiver (*op. cit.*) from which the figure is taken.

from data on the wind stress distribution over the ocean and some effort has been devoted to a more detailed knowledge of this important parameter (Leetma & Bunker *J. mar. Res.* **36**, 311; 1978). Application of these considerations to the equatorial zone leads to upwelling rates of $15\text{--}20 \times 10^6 \text{ m}^3 \text{ s}^{-1}$ for the Atlantic Ocean which means that the upward flux of water into the surface layer, distributed over the entire Equatorial Atlantic Ocean, amounts to about one quarter of the transport of the Gulf Stream along the American coast. In a recent paper by Broecker, Peng and Stuiver (*J. geophys. Res.* **83**, 6179; 1978) the same order of magnitude is derived from the distribution of radiocarbon which entered the ocean after the bomb tests between 1955 and

1965. Their result is of particular interest because it represents a method of assessing upwelling rates which is completely independent of any meteorological parameter and, if it can be accepted as reliable, could provide a valuable reference value for other calculations.

Broecker, Peng and Stuiver start from the fact that the radiocarbon content of the Equatorial Atlantic Ocean is low by a factor of about 4–5 compared with the temperate zones and proceed to consider a number of models on the assumption that the water of the surface layer in the equatorial zone is removed sideways into the temperate zones and replaced by upwelling. In the simplest of their models the equatorial zone is treated as a well-mixed homogeneous layer of 150 m depth between 15°N and 15°S . The choice of the lateral boundaries seems natural from the observed bomb radiocarbon distribution (see Fig. 1). In the vertical, other models use a succession of layers with a 100 m top layer and three 50 m layers below. The resulting upwelling rates vary between 15.6×10^6 and $20.2 \times 10^6 \text{ m}^3 \text{ s}^{-1}$.

Encouraging as these results might seem, the problem with them is that the models could well be called an oversimplification of the actual situation. It is known and has been reported in *Nature* by Düing *et al.* (257, 280; 1975) in a review of the GATE Equatorial Oceanographic Experiment that

the equatorial current system between 15°N and 15°S does not display a simple homogeneous structure (Fig. 2). Broecker, Peng and Stuiver acknowledge the fact and state that their results should be taken as averages over the entire area. It might well be questioned whether an average over two westerly currents and three easterly ones has any significance. More important is the neglect of all zonal transport in the model. The authors calculate, on the basis of their upwelling rate, a vertical velocity of about 30 m yr^{-1} and a residence time of 4.7 yr for the water in the surface layer. Now, even a modest flow of 25 cm s^{-1} crosses the Equatorial Atlantic from east to west (or, in the Undercurrent and in the Countercurrents, from west to east) within less than 300 d. This shows that there is an appreciable inflow of water into the area by advection and that most of the water which enters the surface layer from below at a rate of 30 m yr^{-1} leaves the area at the eastern or western ends rather than through the poleward boundaries. The effect can of course be accounted for by assuming a higher upwelling rate. But this would almost certainly result in a discrepancy between the results of the two independent methods.

It seems, then, that we are still some way from reliable estimates of upwelling rates. The proposal of Broecker, Peng and Stuiver to use radiocarbon observations for an independent calculation is a very valuable one. Bomb radiocarbon concentrations will remain above natural background levels for another decade at least. It is certainly worth collecting more radiocarbon information to provide a good data base for an improved model of equatorial upwelling rates. □

A hundred years ago

Tides in the Bay of Fundy

HAVING resided for some years in the neighbourhood of this bay, I am able to give a little information respecting its tides. The bay splits into two at its inner end. One of these branches leads through a narrow channel into the broad basin

of Minas. The other, called Chegnecto Bay, is not interrupted by any such contraction, and is therefore more favourable for the formation of very high tides. This bay itself divides at its upper end into two, and one of these, called Chepody Bay, contracts very gradually for some thirty miles inland, forming the estuary of the Petitcodiac River. This is the place where the highest tides occur, and as far as I have been able to learn, their maximum height is 70 feet. A powerful "bore" is formed by the incoming waters. The captain of the steamer *Emperor*, which plied between St. John, N.B., and Windsor, N.S., informed me that the highest tide in any part of Minas Basin was about 55 feet.

A PETROLEUM spring, one boring of which has yielded 2,000 kilos in twenty-four hours, has been discovered at Pohar, in Austrian Poland.

ACCORDING to the report of H.M.'s Consul for Hiogo and Osaka, the Japanese claim that petroleum has been known in Japan for over 1,200 years, and it would certainly be curious if the numerous springs which exist in certain localities should have escaped notice in their immediate neighbourhood. It is doubtful, however, whether it was ever utilised, and certainly no attempt was made to refine it before the arrival of foreigners. From *Nature* **19**, 20 March, 458, 473; 1879.

Neogene relative motion between the Pacific plate, the mantle, and the Earth's spin axis

Stephen R. Hammond, David Epp & Fritz Theyer

Hawaii Institute of Geophysics, University of Hawaii, Honolulu, Hawaii 96822

The northward rates of motion for the central equatorial Pacific during the past 24 Myr vary between ~ 20 – 30 mm yr^{-1} based on the migration of sedimentary facies, $\sim 30 \text{ mm yr}^{-1}$ based on the age and orientation of the Hawaiian ridge, and ~ 50 – 60 mm yr^{-1} based on palaeomagnetically determined sediment and basalt palaeolatitudes. To resolve the differences between hot spot and palaeomagnetic results we may need to invoke a long-term drift in the orientation of the geomagnetic field, or a northerly component of motion of the Hawaiian hot spot relative to the Earth's spin axis.

SIGNIFICANT differences between Neogene rates of motion of the Pacific plate relative to: (1) the Hawaiian hot spot, (2) the Earth's spin axis determined from palaeomagnetic data, and (3) the Earth's spin axis deduced from the distribution of equatorial sediment facies, suggest that one or more of the assumptions inherent in each method may be invalid.

Calculation of palaeolatitudes from palaeomagnetic data is usually based on the assumption that, when averaged for several thousand years, the Earth's magnetic field approximates that of a geocentric dipole coincident with the Earth's spin axis. This assumption is supported by palaeomagnetic results such as those of Opdyke and Henry¹, which are based on a worldwide distribution of sediment cores. Other studies conclude, however, that the time-averaged geomagnetic field is better represented by a dipole field slightly displaced into the Northern Hemisphere², or by a pair of unequal axial dipoles³. If either of the latter two results is valid, then palaeolatitudes determined assuming geocentricity will be systematically in error. At low latitudes, however, there is little difference between the geocentric and nongeocentric models in terms of the rate at which field inclination varies with latitude. Because most of the palaeomagnetic data used in this study are from latitudes of $< 10^\circ \text{ N, S}$, the choice of models has no significant effect on palaeomagnetically determined rates of plate motion, and, therefore, cannot be the source of discrepancy between palaeomagnetic results and either hot spot or facies migration results. It is not known whether the average pole positions of the geomagnetic field have remained coincident with the geographic poles over periods of time exceeding several tens of thousands of years. At present, however, there is no evidence of long-term net motion of the north geomagnetic pole towards the Pacific, which is the direction of movement that would be required to reconcile the present palaeomagnetic results with the less rapid northward rates of Pacific plate motion relative to the Hawaiian hot spot.

Other factors that may alter or obscure initial palaeomagnetic

remanence and thereby produce spurious palaeolatitudes, are magnetic overprinting, caused by chemical alteration in either rocks or sediments, and in non-indurated sediments, acquisition of systematic inclination error, caused by post-depositional grain rotation and compaction. Chemical alteration is usually recognised as systematic differences between the direction or magnitude of normal and reversed intervals within a magnetostratigraphic section, or by the behaviour of the remanent magnetism during alternating-field demagnetisation analysis. No such evidence of chemical alteration is observed in the present palaeomagnetic data, and Hammond *et al.*⁴ have shown that there is no discernible compaction-related rotation of palaeomagnetic vectors in equatorial Pacific pelagic radiolarian-rich clays as old as 30 Myr. Their results showed consistent inclination trends within individual chronologically overlapping cores recovered north and south of the Equator.

The present distribution of relatively thick equatorial sedimentary facies, originally deposited in equatorial regions of upwelling and high biological productivity, has been used^{5–8} as another means to determine the Cainozoic motion of the Pacific plate relative to the Earth's spin axis. Isopachs delineating progressively older sediments are systematically offset to the north. Poles and rates of rotation are determined by backtracking the locus of maximum sediment thickness, for a discrete time interval, to its original equatorial deposition site. It is difficult to quantitatively assess the reliability of plate motions based on the migration of equatorial sedimentary facies other than by their consistency with other independently derived results. The accumulation of sediment on a moving plate is governed by the interaction of dynamic factors including upwelling-induced surface productivity, the width of the area of upwelling, erosion, and CaCO_3 solution. Relatively brief hiatuses within a sedimentary section, due to nondeposition, dissolution, or erosion, for example, may be cumulatively significant as well as difficult to detect. Van Andel and Whaley⁹ have pointed out that maxima and minima in rates of sedimentation can vary in response to factors unrelated to the latitude of the deposition site. There is little doubt, however, that the distribution of equatorial sedimentary facies is strongly influenced by the motion of the Pacific plate.

According to the hot spot hypothesis of Wilson^{10–12} and Morgan¹³, linear volcanic chains are formed as the sea floor moves over magma sources below the lithosphere. Morgan¹³ originally defined 20 hot spots and postulated that they were surface manifestations of convection plumes that originate near the core-mantle boundary. He also suggested that hot spots might move relative to each other at maximum rates of about 5 mm yr^{-1} . Recent reconstructions (refs 14–17 and Morgan, personal communication) confirm that little or no relative motion is required between hot spots, suggesting that hot spots can be used as a global coordinate system to which plate motion

can be referred. Volcanic chains that were formed at hot spots can be used to determine the motion of plates relative to this coordinate system. Because the Hawaiian ridge–Emperor seamount chain is the most prominent and best studied hot spot trace on the Pacific plate, it provides the best estimate of the plate's motion with respect to a hot spot coordinate system. Epp's¹⁸ analysis used only this volcanic chain, and, therefore, made no *a priori* assumptions about the relative age of other volcanic chains on the Pacific plate. The poles Epp¹⁸ found, however, seem to be representative of other hot spot traces on the plate, suggesting that there has been little relative motion among Pacific hot spots for at least the past 25 Myr. In other studies, Clague and Jarrard⁷ used the Hawaiian, Cook–Austral, and Guadalupe chains to determine a pole position; their analysis was amended by Dalrymple *et al.*¹⁹ to incorporate a revised radiometric age for Midway. Minster *et al.*¹⁴ determined a pole position and rate of rotation from a systematic inversion of all available relative motion data and azimuths of hot spot traces. The poles and rates of rotation thus determined can be used to determine the northward motion of the Pacific plate relative to the hot spot coordinate system.

Palaeomagnetism of Pacific deep-sea sediments

The northward motion of the Pacific plate during the late Mesozoic and the Cenozoic seems to be responsible for the discrepancies, found for older sediments and volcanic rocks, between measured palaeomagnetic inclinations and those characteristic of the present latitude of the sampling site. Latitudinal migration of the Pacific plate has been inferred from results of paleomagnetic surveys of Pacific seamounts²⁰, palaeolatitudes from drilled basalts²¹, and palaeolatitudes from both drilled and cored sediments^{4,22}.

In the present study 27 chronologically overlapping piston cores, which collectively span the past 25 Myr, have been used to determine the northward motion of the central equatorial Pacific. The cores were recovered from the Central Pacific Basin (average depth 5.0–5.5 km), where extensive erosional surfaces make possible the recovery of relatively old sediments by piston coring²³. All of the cores contain homogeneous brown,

Fig. 1 Progressive increase, with increasing age, between the observed mean palaeolatitude and the coring site latitude (Δ latitude) for chronologically overlapping cores from the Central Pacific Basin. Vertical bars represent the standard error for the mean palaeolatitude of each core. Age span and Δ latitude value for the cores are shown in Table 1.

radiolarian-rich clays (Table 1). Average core length is about 13 m and average sediment accumulation rate is about 3 mm per 10^3 yr. This relatively low accumulation rate means that each sample from the cores contains, on the average, a depositional record spanning about 6,000 yr. Magnetic secular variation is therefore largely averaged out within single samples.²⁴ The cores were dated by correlating their radiolarian and magnetostratigraphy to the time scale of Thayer and Hammond^{25,26}. The K76 core series (Table 1; Fig. 1) is fully orientated, which allows an unambiguous determination of both polarity and the hemisphere in which the cores were deposited²⁷.

The stability of depositional magnetic remanence was established by standard alternating-field partial demagnetisation analysis of at least six samples from each core^{4,28}. After the stable remanence was resolved, individual inclination values in each core were converted to palaeolatitudes by use of the geocentric dipole formula. A mean palaeolatitude was calculated for each core by first determining the mean palaeolatitude for each polarity interval, and then dividing the sum of the absolute values of the polarity interval means by the total number of polarity intervals.

The mean palaeolatitude for each core was normalised for its core site latitude⁴ and then plotted against the mean age of the core (Fig. 1). Each core was sampled at 10-cm intervals, so the average northward rate indicated in Fig. 1 is based on nearly 3,500 discrete palaeolatitude determinations. A linear regression of the differences between mean palaeolatitude and coring site latitude (Δ latitude) versus mean age, assuming mean core age to be the independent variable, indicates an average rate of palaeolatitude change for the central Pacific of about 64 mm yr⁻¹ throughout the Neogene. This rate agrees with that determined in a similar manner by Hammond *et al.*⁴ (using seven cores) for the interval 0 to –13 Myr, but is considerably slower than their previously determined rate of about 110 mm yr⁻¹ for –13 to –21 Myr. The distribution and resolution of the present data preclude a reliable determination of variations in the rate of northward motion during the Neogene, although such variations may have occurred as a result of reorganisation of plate boundaries and change in the rate and/or direction of seafloor spreading. At present, palaeomagnetic data are insufficient for reliable estimation of an average northward rate of plate motion during the Palaeogene, but the Neogene rate shown in Fig. 1 is compatible with approximately 30° northward displacement of the Pacific plate since the Cretaceous^{5,20}.

Comparison of results

Since northward rates of motion for different locations on a plate vary with distance and azimuth to the pole of rotation, DSDP Site 166 (3.76° N, 174.08° W), located in the Central Pacific

Table 1 Cores taken from the Central Pacific Basin

Core no.	Coring site	Water depth (m)	Recovery (m)	Age span of core (Myr)*	Δ latitude (deg)

	67° N	59° W	25-50	0.25
Lancelot and Larson	67° N	45° W	0-40	0.5

Basin (and central to the location of the palaeomagnetically studied sediment cores), was chosen as a convenient location where palaeomagnetically-derived northward rates of plate motion could be compared with the northward rates of motion determined from migration of sediment facies and from hot spot traces. Using the pole positions and rates of rotation determined by the investigators listed in Table 2, Site 166 was rotated from its present location to its position at -24 Myr. In Fig. 2 the change in latitude (Δ latitude) of Site 166 determined by these rotations is compared with the palaeomagnetically determined change in latitude. The palaeomagnetic data were fit by a straight line which indicates a northward motion of 64 mm yr⁻¹. The other rotations show a slight increase in the northward rate of motion with age which results from the change in position of DSDP Site 166 relative to the poles of rotation. The northward rates determined from the hot spot analyses of Epp¹⁸, Clague and Jarrard⁷ together with Dalrymple *et al.*¹⁹, and the plate inversion analysis of Minster *et al.*¹⁴ are similar and about 30 mm yr⁻¹. The consistency of these analyses supports the result.

The sediment facies analysis by van Andel⁶ requires a similar northward motion, 33 mm yr⁻¹, at Site 166. The more recent equatorial facies analysis of Lancelot and Larson⁸, on the other hand, indicates a considerably slower northward rate, about 20 mm yr⁻¹, for the same time interval and location. Winterer's⁵ sediment facies analysis (not shown) yields a northward velocity of about 43 mm yr⁻¹.

There are relatively few other Neogene palaeomagnetic results from the Pacific plate which can be compared with the foregoing results. Grommé and Vine²⁹ determined an average palaeolatitude from samples of 13 basalt flows recovered in a

**Fig. 2** Change in latitude versus age for DSDP Site 166 from: A, sediment palaeomagnetism; B, Minster *et al.*¹⁴; C, Epp¹⁸; D, Clague and Jarrard⁷ with a rate of rotation determined by Dalrymple *et al.*¹⁹; E, van Andel⁶; F, Lancelot and Larson⁸.**Fig. 3** Change in latitude versus age for Midway. Midway data from Grommé and Vine²⁹ and Dalrymple *et al.*¹⁹. Other lines from the same sources as in Fig. 2.

deep drill core from Midway Island (28.2° N, 177.6° W). Thus Midway is another location where the Neogene northward motion of the Pacific plate determined by the above analyses can be compared (Fig. 3). The northward velocities at this location differ only slightly from the Site 166 results, and the discrepancies between the various analyses are just as pronounced. The palaeomagnetic data represented by point A in Fig. 3 indicate that Midway Island has been displaced northward by ~13° during the past 27 Myr. Using the average rate of northward displacement of Midway during this interval of time (52 mm yr⁻¹) to constrain the Hawaiian ridge model of Epp¹⁸, an average northward velocity, for the Central Pacific Basin, of 55 mm yr⁻¹ is obtained. Thus the Midway palaeomagnetic rate is consistent with the Central Pacific Basin palaeomagnetic results in that it also is significantly more rapid than the other rates shown in Fig. 2.

Results of a recent study by Marshall³⁰, of mid-Cretaceous to mid-Miocene basalts recovered at several north Pacific DSDP sites, are consistent with the Midway and the Central Pacific Basin palaeomagnetic results inasmuch as they, too, indicate a higher rate of northward plate motion than do hot spot and sediment facies studies.

Discussion

The results in Figs 2 and 3 show significant and consistent discrepancies among independently derived Neogene rates of northward motion of the Pacific plate. Palaeomagnetically derived rates are roughly twice as fast as those determined by backtracking equatorial sedimentary facies to their original deposition sites.

The sediment facies analyses describe the motion of the plate relative to the spin axis, and therefore should be consistent with the palaeomagnetic analyses. As shown in Figs 2 and 3, however, the predicted rates of northward motion based on sediment migration are considerably slower than those based on palaeomagnetism of both sediments and basalt. The inherent difficulties in sediment facies analyses discussed above may be responsible for the differences among the van Andel⁶, Lancelot and Larson⁸ and Winterer's⁵ results as well as the difference between the sediment facies results and the palaeomagnetic results. If palaeomagnetically determined rates do provide an accurate indication of plate motion relative to the spin axis, the agreement between facies results and those based on hot spots may be fortuitous.

The palaeomagnetically derived rate of about 64 mm yr⁻¹ appears reliable from the standpoint of the consistency and the

large amount of data from which it was determined. Likewise, the agreement between the results of Epp¹⁸, Minster *et al.*¹⁴, and the combined work of Clague and Jarrard⁷ and Dalrymple *et al.*¹⁹ strongly indicates that 30 mm yr⁻¹ is a reliable rate for the northward motion of the Pacific plate relative to the hot spot coordinate system. If the Earth's magnetic field is fixed with respect to the spin axis and the palaeomagnetic results indicate the true velocity of the Pacific plate with respect to the spin axis, then, to resolve the difference between the palaeomagnetic and hot spot rates, the Hawaiian hot spot must have moved northward relative to the spin axis at an average rate of about 30 mm yr⁻¹. The implications of this motion for the motion of the mantle with respect to the spin axis depends on the origin of hot spots. If hot spots are fixed with respect to the asthenosphere, then any hot spot versus spin axis motion requires only that the asthenosphere move relative to the spin axis. If, on the other hand, hot spots are the surface manifestations of plumes that ascend from the core-mantle boundary³² then the entire mantle must be moving relative to the spin axis. As the total vector of motion of the mantle is unknown, the absolute mantle velocity cannot be determined; however, if this motion is the result of some mantle-wide convection system, there should be southerly motion at some other location. Burke *et al.*¹⁷ found that hot spots in the North Atlantic have moved northward relative to the spin axis, and hot spots in the South Atlantic have moved southward. To conserve matter, the mantle under Asia must be moving southward relative to the spin axis; however, the southward motion of South Atlantic hot spots suggests a more

complicated convection pattern. An intermediate possibility is that different plumes come from different depths in the mantle. This conceivably could allow a complex mantle convection system while retaining the fixed nature of hot spots.

An alternative explanation for the differences between plate motion rates, especially in view of the close agreement between van Andel's⁶ results and the hot spot results, is that the palaeomagnetic results are systematically biased with increasing age. As compaction-related inclination error and tectonic tilting of the Central Pacific Basin can be ruled out, the possibility that the north geomagnetic pole was moving towards the Pacific at a rate of approximately 30 mm yr⁻¹ during the Neogene must be considered. Andrews³² analysis of polar wander during the Mesozoic and Cainozoic indicates that the field was moving relative to the Pacific plate during the Neogene, but the apparent motion was in essentially the opposite direction needed to reconcile the palaeomagnetic, sedimentary facies, and hot spot results. If Andrews³² conclusion is correct, the palaeomagnetic rates, relative to the Hawaiian hot spot, are even more rapid than indicated in Figs 2 and 3.

This work was supported, in part, by the Office of Naval Research. Additional support, especially for the stratigraphic study of the K72 and K76 piston cores, was provided by the NSF under grants DES74-19504 and OCE76-02187. The Hawaii Institute of Geophysics Core Laboratory is supported by the Office of Naval Research and the NSF under grant OCE77-20050. D. E. was supported by the NSF as part of the Hawaiian Ridge Study (OCE76-82056). We thank Dr J. Morgan for his helpful comments.

Tidally generated internal wave packets in Massachusetts Bay

Loren R. Haury

Scripps Institution of Oceanography, La Jolla, California 92093

Melbourne G. Briscoe & Marshall H. Orr

Woods Hole Oceanographic Institution, Woods Hole, Massachusetts 02543

Observations in Massachusetts Bay of high-frequency internal wave packets indicate that they are caused by lee waves generated outside a submarine bank at the Bay's seaward margin during ebb tide. The lee waves propagate into the Bay as the tide turns to flood, steepen nonlinearly, and develop into the packet. A 200-kHz acoustic back-scattering system detected the evolution of the packets. Large overturning events were observed acoustically and in density profiles. Plankton distributions undergo strong vertical displacements and mixing associated with the wave packet passage.

HIGH-FREQUENCY internal wave packets in Massachusetts Bay^{1,2} (Fig. 1) have been studied to understand their generation and propagation, to describe the biological variability in the plankton caused by their passage, and to further evaluate the use of high-frequency acoustic backscattering systems as remote sensors of fluid processes in the ocean. Previous work on the physical properties of internal wave packets generated by tidal flows over topography¹⁻⁶, by atmospheric forcing of internal surges^{7,8}, or from unknown causes⁹⁻¹¹, has concentrated on packet propagation. Fewer generalisations seem possible about packet generation because it is more dependent on the particular forcing field and the local topography. D. Farmer and J. Smith (personal communication) and also T. Maxworthy¹², have developed conceptual models for the topographical generation

Fig. 1 Experimental area in Massachusetts Bay. A and P mark mooring sites. ●, Locations of Sippican T-11 expendable bathythermograph profiles. △, Positions at which internal wave packets were acoustically observed. *, Position at which acoustic record of Fig. 4a was obtained. Site P was a subsurface mooring (float at 22 m; water depth nominally 35 m) with a General Oceanics 2011 film-recording current meter at 25 m depth. Site A was a subsurface mooring (float at 22 m; water depth nominally 80 m) with an Aanderaa RCM4 current meter at 25 m depth, and a surface mooring carrying an Aanderaa TR1 thermistor chain with sensors at 3-m intervals between 5 and 32 m. ○, The deployment location of VCM2 (Fig. 3); VCM3 (Fig. 3) was very near site A.

Fig. 2 Schematic diagram of internal wave packet generation as a lee wave during ebb tide over Stellwagen Bank (a), followed by nonlinear steepening after the tide turns (b). The turn of the tide allows the packet to propagate over the bank towards shore. Undulations then develop behind the steep front (c and d). See Fig. 4a for 200-kHz acoustic record of a developed packet.

Fig. 3 Temperature and depth records from a modern version of the Swallow float vertical current meter (VCM)^{17,18} at positions shown in Fig. 1 *a*, VCM2 on 31 August; *b*, VCM3 1 September. VCM2 drifted about 0.6 km WSW and VCM3 about 2.3 km SSW during their respective deployments. The VCM3 trace shows the two internal wave packets that followed the single packet of the VCM2 trace. The VCM internally records temperature, pressure and rotation (vanes on the instrument rotate it about a vertical axis when there is vertical flow relative to the instrument). An acoustic signal from the VCM allows shipboard tracking while the instrument is deployed. Because the temperature is nearly constant at 10.2 °C (sensor time response <1 min), and because the rotation showed insignificant vertical currents past the VCM (less than 20 cm vertical water displacement), the VCM depth accurately portrays the fluctuating depth of the 10.2 °C isotherm. The record of isotherm depths from site A-moored thermistor chain during the VCM3 packet and results of CTD vertical profiling both substantiate this interpretation.

of internal wave packets by a time-varying tidal flow which are good descriptions of our observations in Massachusetts Bay. Specifically, the ebb tide flow over Stellwagen Bank (Fig. 2) generates a lee wave on the eastern side. When the tide turns to flood, the lee wave propagates into Massachusetts Bay (heading about 240 °T), steepens due to nonlinear effects¹³, and develops undulations due to an imbalance of dispersion and nonlinear effects¹⁴. In analogy to other locations^{3,4}, we would expect to observe wave packets outside Stellwagen Bank due to lee waves inside during flood tide. As most of our observations were inside the Bank, we did not see outgoing waves. They may not be present because of the asymmetry of the Bank and tidal flow.

Lee wave propagation

The occurrence of lee waves on the eastern side of Stellwagen Bank depends on an ebb tide flow with a subcritical internal Froude number¹⁵. Our measurements, together with those of ref. 16, showed the flow to be subcritical using either a two-layer fluid or a continuous-gradient model. The presence of the lee waves was substantiated by a transect of 11 bathythermographs across the Bank during ebb tide (Fig. 1). The 10 °C isotherm (in the thermocline) descended from 8 m over the Bank to 20 m at about 7 km to the ENE with oscillations that may be the expected lee waves.

Fig. 4 *a*, 200-kHz acoustic record of an internal wave packet observed at the position marked * in Fig. 1. The period of the waves are Doppler shifted by the ship's speed of about 2.5 knots (128 cm s^{-1}) as it travelled from the rear to the front of the packet parallel to the packet's propagation direction (240°; left to right in figure). The seasonal thermocline is displaced by 30 m (arrow 1) and the stratified point scatterers (zooplankton?) at 30 to 40 m are displaced more than 20 m (arrows 2 and 3). The heavy acoustic backscattering in the vicinity of arrow 4 and extending in an oscillatory pattern throughout the figure is possibly caused by turbulent mixing in the thermocline. The asymmetry of the wave field, with narrow troughs and broad crests, is determined by the depth of the mixed layer²⁰⁻²¹. Similar asymmetrical waves have been observed acoustically in the lower atmosphere²². The heavy scattering near 75 m is probably caused by euphausiid and mysid shrimp. The oscillations in bottom depth (arrows 5 and 6) are due to variations in the travel time of the sound pulses resulting from the thermal structure of the waves; that is, the water column above arrow 6 is mostly cold (slower speed of sound). *b*, The 200-kHz acoustic record of overturning instabilities associated with the internal wave packet (propagating from right to left) at site A (Fig. 1) between 11.30 and 11.41 LT, 30 August 1977. This portion shows two overturning events; the direction of overturning (left to right) is opposite that of packet propagation. Superimposed are the corroborating density profiles obtained by repeated vertical casts of the CTD. The instrument's path is seen as the oblique traces in the acoustic record. The ship was drifting during the observations. The winds during these observations (and for most of the experiment) were $<2 \text{ m s}^{-1}$. *c*, Profiles of temperature and chlorophyll fluorescence for the same wave packet as in Fig. 4*b*, but between 10.58 and 12.10. The vertical exaggeration is about twice that of the acoustic record; isotherms and 'isofluors' are drawn between profile data points using the acoustic imagery as a guide. The wide hatching depicts fluorescence values greater than 37.5 arbitrary units, the narrow hatching greater than 40.0 units. ●, Within the hatched areas are at the depth of the chlorophyll maximum. The light level at the chlorophyll maximum layer before the packet arrival was 18% of ambient (range 14–22%) [Secchi Disk depth: 11 m, extinction coefficient $k = 0.17$]. Immediately after arrival, the mean level was 3% (range 1–13%). Four hours later, the mean light level was still only 3.5%. During the time shown the ship was drifting with the local currents such that the observations (11.15 to 11.30 LT) are along the first trough of the wave packet, then slowly scanning back (after 11.30) through the packet as the current turned from west to SSW.

Although we believe that only lee waves were formed over Stellwagen Bank during our observations, certain conditions (sufficiently high Froude number) could generate a turbulent internal hydraulic jump. This has been observed in fjords with blocking sills³. The potential thus exists at Stellwagen Bank for strong biological effects due to the mixing. In its absence, however, the propagation of the lee wave into Massachusetts Bay seems to be a wave phenomenon with no significant net transport of water or plankton by the waves alone.

Two sets of data (Fig. 3) support the picture of wave propagation shown in Fig. 2b and c. The 10.2°C isotherm at the front of a newly developed wave packet (VCM2) initially deepens at about 18 cm s⁻¹, with few oscillations occurring during the next hour. At a later stage of wave development (VCM3), the isotherm deepens at 38 cm s⁻¹ with strong following oscillations. Numerous 200-kHz acoustic records¹⁹ obtained between Stellwagen Bank and site A also support the model. Neither of the VCM floats was transported by the wave packets; this supports the conclusions of the preceding paragraph.

The propagation of internal wave packets has been described by a form of the Korteweg-de Vries equation^{2-4,7}. Possible solutions include a modulated, undulatory wave packet in which the modulation has the form of solitary waves. The record of isotherm depth from VCM3 (Fig. 3) fits this solution; the 8–10-min period oscillations have a modulation envelope of about 90 min period; about three envelope oscillations are distinguishable. Long period modulations are also present in the thermistor chain record from site A.

Wave packets were repeatedly observed with the acoustic system (see Fig. 4a) as they propagated through Massachusetts Bay. Some of these acoustic records show large shear instabilities (Fig. 4b). These are similar to turbulent shear flow in the atmosphere²³ and laboratory²⁴⁻²⁶. Densities calculated from vertical profiling conductivity-temperature-depth (CTD)²⁷ casts through two events (Fig. 4b) show strong inversions. This supports the interpretation of these structures as overturning instabilities. The direction of overturn, being opposite to the wave propagation direction (Fig. 4b), argues for a shear opposed to the wave propagation²⁶, that is, the surface velocities are

against the waves, the deep velocities are with them. We have no direct measurements of shear, but note that 2×10^{-2} s⁻¹ levels have been observed at the site¹⁶.

Redistribution of chlorophyll and zooplankton

Figure 4c shows the overturning events reflected as inversions in the vertical profiles of temperature and chlorophyll fluorescence. These events redistribute the chlorophyll and zooplankton. As no nutrient data were collected, we do not know if the surface layer is enriched with nutrients mixed from below. Because the geographical regions within which internal waves break are restricted both spatially and temporally, the vertical effects of mixing would be reflected in heterogeneous horizontal distributions of chlorophyll, zooplankton, and, if nutrients are affected, primary production.

Phytoplankton production may be affected by the interaction of the diel light cycle with the chlorophyll depth variations caused by internal wave packets acting over the semi-diurnal tidal cycle of 12.4 h. A mathematical model of internal wave effects on a chlorophyll maximum layer at the depth of the 10° isotherm showed the maximum daily peak illumination level (12 h day length) experienced during a 2-week tidal cycle varies by a factor of 2.3, whereas the minimum total daily integrated illumination is 67% of the maximum. In these conditions, production is affected both by simple light limitation over the 2-week tidal cycle²⁸ and by the more complex physiological effects of rapid light variation during any one day²⁹.

Zooplankton distributions were sampled at site A using a Longhurst-Hardy plankton recorder (LHPR)³⁰. These data and the simultaneous acoustic records showed no evidence for any behavioural response rapid enough to suggest that the plankters are other than passive markers of the wave field. Plankton distributions taken by the horizontal LHPR tows, however, do vary markedly with the passage of internal waves. In Fig. 5, the abrupt change in the temperature and salinity signatures of the internal waves at sample 50 are mirrored by chlorophyll fluorescence and appendicularians, but not by amphipods and

Fig. 5 Data from the Longhurst-Hardy plankton recorder tow taken at constant depth (17.5 m) through the first part of the internal wave packet at site A between 09.31 and 09.52 LT 28 August 1977. The record begins just after the leading edge (first trough) of the packet passed the ship. The direction of the tow was into the wave packet propagation; the tow speed was about 75 cm s⁻¹; tow length 980 m; sample length 12.2 m; mean volume filtered per sample 0.25 m³ (no net was used preceding the recorder box). The depth of the tow, temperature, salinity and chlorophyll fluorescence records are from the CTD and *in situ* fluorometer mounted on the plankton recorder vehicle. Other tows (oblique), taken to determine vertical distributions, showed the appendicularians and amphipods to be restricted to the warmer surface waters, whereas the *Calanus* copepodites occurred in greatest abundance in deeper water of temperature less than about 12–14 °C.

Calanus copepodites. Another tow taken at 1.5 m through the first three crests following the leading edge of an internal wave packet showed abundant *Calanus* copepodites at the surface in the third crest; water of almost the same temperature, but with few copepodites present, occurred at the surface in the preceding two crests. The 200-kHz acoustic records accompanying all the tows provided a valuable picture of the vertical distribution throughout the water column of scattering from both organisms (that is, point scattering) and from possible temperature and velocity fine structure.

Isotherm following has been suggested as a way of removing the confounding effects of internal waves on studies of plankton pattern³¹. The rapid rate of isotherm depth variation (see Fig. 3) makes such a task very difficult. Our observations show that variability of periods similar to those of the internal waves is effectively removed, but there is increased short period variability due to unavoidable excursions above or below the target isotherm depth and the impossibility of following isotherms in regions of overturning. Long period (greater than the internal wave period) variations in horizontal abundance, however, are clearly evident; these would not be easily detected by towing at constant depth.

Conclusions

The generation of the wave packets can be explained by the models of Maxworthy and Farmer (Farmer's internal hydraulic jump is more violent than our observations) and the steepening and propagation are consistent with earlier studies. We see suggestions of envelope behaviour in the modulation of the wave packets, and our acoustic observations show large overturning instabilities substantiated by density inversions in the CTD profiles. Strong inhomogeneities in the vertical and horizontal plankton distributions are caused by the passage of the internal waves; the waves also have potential effects on primary production in the Bay. Acoustic records (200 kHz) are particularly valuable in providing a real-time kinematic view of

the scattering field due to the combination of plankton and internal waves.

We thank B. Bardsley, S. Boyd, J. Brooks, T. Chereskin, D. Crowell, J. Dean, W. Dewar, J. Douth, A. Gargett, E. Hays, F. Hess, S. Hoercher and P. Wiebe for their assistance, and the Naval Underwater Systems Center, Newport, Rhode Island, and the US Coast Guard Air Detachment, Otis Air Force Base, Massachusetts, for their cooperation. Design and construction of the acoustic systems was funded by NORDA contract no. N00014-77-C-0196 and NOAA contract no. 04-6-158-40072. This work was supported by NSF grant no. OCE77-08682.

Pliocene footprints in the Laetoli Beds at Laetoli, northern Tanzania

M. D. Leakey & R. L. Hay*

P.O. Box 7, Ngorongoro, Tanzania

Recent excavation of the tuffs of the Laetoli Beds in Tanzania has revealed the presence of a large variety of footprints from the Pliocene. Many of these prints can be correlated with fossilised remains of Pliocene animals found in the same area.

It was stated previously¹ that the name Laetoli would be used in preference to either Garusi or Vogel River for the area where the Laetoli Beds are exposed. Laetoli, as stated then, is an anglicisation of the Masai word Laetoli and was first used by Kent². The Tanzanian authorities have now asked that the term Laetoli should be dropped in favour of Laetoli. The name Laetoli will be used for the area, but the Pliocene deposits will continue to be known as the Laetoli Beds, as established in 1976¹.

The Laetoli Beds (Figs 1, 2) are dominantly tuffs which have a maximum known thickness of 130 m and are divisible into upper

and lower units. Nearly all the fossils have come from the upper unit which is 45-60 m thick.

In 1975 three marker tuffs had been identified in the upper unit of the Laetoli Beds¹. Since then, more than a dozen widespread air-fall tuffs (Fig. 3) have been recognised, permitting detailed correlations.

Description of the footprints tuff

The footprints tuff is divisible into two units of differing lithology and structure. The lower unit, 7-8.6 cm thick, is relatively uniform in thickness and is characterised by widespread ash layers of even thickness, commonly with rainprinted surfaces. The upper unit, generally 5-7 cm thick, thins over the higher areas of the lower unit and thickens in depressions to eliminate the undulations preserved by the mantle bedding of the lower unit.

Several unusual features of these tuffs can be explained by composite ash falls of natrocarbonatite ash and melilitite lava globules. The ash must have been cemented rapidly to have

* Present address: Department of Geology and Geophysics, University of California, Berkeley, California 94720

Fig. 1 Map of the southern Serengeti and volcanic highlands showing the position of the Laetoli area.

prevented erosion of the sand-sized lava globules by wind in this semi-arid climate in which 80–85% of the sediment was wind-worked. Natrocarbonatite ash would have dissolved incongruently in rainfall to yield soluble carbonates, which would have crystallised under the heat of the Sun to cement the ash layer in a few hours.

Footprints were made on at least six different surfaces but are by far the most common at two levels (Fig. 4). Prints of birds and

hares are common to all levels, but prints more than about 10 cm in diameter have been found only in the upper unit. Particularly striking is the number of elephant prints in the higher levels compared to their apparent absence below.

On the basis of the available evidence a tentative history of the footprint tuff begins near the end of the dry season and continues into the rainy season. The first showers of ash fell on a relatively bare, nearly flat landscape with scattered *Acacia* trees. The ash layers which constitute the lower unit were cemented by intermittent showers near the beginning of the rainy season. A few times between showers extruded eolian sediments, together with some of the air-fall ash, were redeposited by wind. The sharp contact at the base of the upper unit may mark the onset of the rainy season. Stratification in the upper unit is compatible with sheetwash produced by heavy showers, but is unlike that of the lower unit in which individual ash layers vary little in thickness over a distance of 5 km. The smaller amount of calcite in the upper unit may have resulted from either heavy rains or a smaller original content of carbonatite ash, or both. Thus, the abrupt appearance of footprints of elephants and other large animals in the upper unit may represent, at least in part, their migration which accompanies the rainy season.

The 1975 and 1976 field seasons at Laetoli were devoted to study of the geology of the area and the collection and excavation of fossil vertebrates and molluscs from the Laetolil Beds and later deposits. The age of the upper, fossiliferous part of the Laetolil Beds was established at 3.6–3.75 Myr (ref. 1).

While visiting the Laetoli camp during 1976 Dr Andrew Hill observed a number of depressions in the surface of a fine-grained tuff exposed in a river bed. These proved to be footprints of birds and mammals ranging from elephant and rhinoceros to carnivores and hares, which had been exposed by natural erosion and weathering.

The first site where footprints were observed (site A in Fig. 2) lies just south of the Garusi River in fossil Locality 6. An area of ~490 m² has been exposed by natural erosion and by excavation. To the south-west, at a second site (C) there are ~156 m² of the footprint-bearing tuff exposed. Both these localities were studied in detail in 1977. Five further areas where the footprint-bearing tuff is well exposed are also known but have not yet been completely studied.

Fig. 2 Map of the fossil localities and footprint sites at Laetoli.

Table 1 Mean percentages of mammalian specimens from various sites

Bovidae		Equidae	4.4%
(of which 15.1% are		Suidae	3.6%
<i>Madoqua</i> , dik-dik)	43%	Proboscidea	3.4%
Lagomorpha	14.4%	Rodentia	3.3%
Giraffidae		Carnivora	3.1%
(including both a large			
and small species, as			
well as <i>Sivatherium</i>)	11.2%		
Rhinocerotidae	9.7%		

Avifauna, Cercopithecidae, Hominidae and Pedetinae were omitted from this list.

Deeply worn game tracks or pathways can be seen crossing the footprint areas at two sites. These were clearly used repeatedly by animals to reach some objective and on modern behavioural patterns it is likely that they were made by the game going to and from water holes.

Only a proportion of the animals represented in the fossil prints have been identified so far. Investigation of present-day game tracks in National Parks is underway to provide comparative information. In general, however, the fossil record agrees well with the footprints. A Musukuma tracker was employed to assist in identifications. He assisted considerably in identifying to family and generic levels, particularly in the case of Bovidae, which are commonly represented in both the footprint and fossil records.

A partial breakdown of the mammalian specimens recovered from the Laetoli Beds in 1975 was published¹ and may usefully be given here. Additional material was recovered in 1976 and 1977, but the overall proportions of various groups remain close to the first figures (Table 1).

The footprints that have been recorded are briefly described below, with notes on the fossil material where it seems to be related.

Fig. 3 Columnar section of the upper unit of the Laetoli Beds at Locality 1 showing air-fall tuffs and horizons of lapilli and blocks. The present report is based on studies of the lower part of Tuff 7, termed the Footprint Tuff. Tuffs 6, 7 and 8 were designated Tuffs a, b and c by Leakey *et al.*¹. The pholite tuff was designated Tuff d.

Diplopoda

A single track approximately 20 cm long is known at site (A).

Fossil record: a small fragment of fossilised centipede was found at Locality 4.

Avifauna

(1) *Struthio* sp. Two isolated prints at site (A).

(2) *Phasianidae*, cf. Guinea fowl. Numerous tracks occur at all sites, generally in trails of four or more. They compare closely with tracks of the living helmeted Guinea fowl, common in the Laetoli area today. Average length of eight fossil prints 62 mm, of nine modern prints 60 mm.

(3) Similar but smaller tracks, averaging 45 mm in length, possibly of francolin.

Fossil record: numerous fragments of ostrich eggshell are known but no skeletal remains. Clutches of eggs comparable in size to those of modern Guinea fowl have been found at Locality 10.

Primates

Cercopithecidae: Tracks are known at three localities.

At site (C) there is a single trail comprising six hind foot prints with a digit protruding to one side. Each of these prints is accompanied by a roughly circular impression, always to the left (Fig. 5). When first discovered these prints were interpreted as knuckle impressions, but more thorough cleaning has revealed traces of the palms of the hands and they are undoubtedly prints of the forefeet. In the hind feet the longest digit is central and the prints range in length from 20.1 to 14.7 cm with an average of 17 cm. The width varies from 10.9 to 8.1 cm with an average of 9.9 cm (excluding the great toe). Stride length varies from 34 to 46 cm with an average of 41 cm. (Stride is here interpreted as the distance between the posterior margin of successive heel prints of the same foot.)

The second trail is at site (D). It was made by a single animal and is 4 m long. There are prints of both hind and forefeet. All are lightly imprinted on a surface which was clearly wet and slippery when the animal walked over it. The average length of the hind prints is 14.5 cm and of the forefeet prints 11 cm. Stride length averages 27.7 cm. These prints are not only smaller than those at site (C) but are relatively broader, with very narrow heel impressions.

At site (F), in fossil Locality 10, there are at least four sets of tracks going in slightly different directions, as do the tracks of present-day baboons when they move in a troop. The average measurements of the hind feet in each of the four trails range from 15.2 to 10 cm and of the forefeet prints from 7.6 to 4 cm (excluding the great toe).

Fossil record: a number of cercopithecoid mandibles and teeth and a few postcranial fragments have been provisionally attributed to *Papio* sp. and a colobine. Most are as small or even smaller in size than those of a living female baboon, but two mandibular fragments, a calcaneum and the distal ends of a humerus and femur are considerably larger than in any living baboon and compare in size with *Theropithecus oswaldi*. The difference in size between the prints described above is compatible with that of the known fossils, although age and sex differences are factors to be considered.

Hominidae: Three trails believed to be hominid are known at sites (A) (Fig. 6) and (G) (Figs 7, 8), in fossil Localities 6 and 8. (1) At site (A) there are five prints in a trail 1.5 m long (Fig. 6). Natural erosion has almost entirely exposed two of the prints, but the remaining three are still filled with matrix of the overlying deposits. The exposed prints are short and broad, 15.5 cm long and 10.5 cm wide. The stride is also short with an average length of 31 cm. The gait was somewhat shambling, with one foot crossing in front of the other. Unlike the cercopithecoid prints, the longest digit is the great toe, situated as in the human foot.

Fig. 4 Generalised columnar section for footprint tuff at site A.

It has been suggested that these prints might have resulted from the superposition of a hind on forefoot impression, or vice versa, either of a quadrupedal animal or a knuckle-walking primate. Careful examination of the original prints *in situ* reveals no indication of superposition, while the last interpretation invokes the hypothetical existence of an animal which is not present in over 5,000 fossil specimens.

(2) At site (G) there are trails left by two individuals travelling north (Figs 7–9). The trails are parallel and ~25 cm apart, too close for the hominids to have walked abreast. They followed the same line or pathway but it is possible that they did not pass by at the same time as there is a noticeable difference in the conditions of the two sets of prints. Those of the smaller individual are sharp and well defined, indicating a firm, compact surface, whilst those of the larger individual, with one notable exception, are blurred at the edges and enlarged, as would be the case if the surface had been dry and dusty. At one point the smaller individual appears to have paused and made a half-turn to the left before continuing in a northerly direction.

In a number of prints the original surface in which they were made has been eroded, leaving only indentations in the underlying deposits. Thus, the measurements of these prints do not accurately reflect the dimensions of the original impressions and are not included.

The site is now being excavated and the trails have so far been found to extend for a distance of 23.54 m. Trail 1 contains 22 prints and Trail 2 contains 12 prints. The average length/breadth of the prints in Trail 1 is 18.5 × 8.8 cm and in Trail 2 is 21.5 × 10 cm. Average stride length in Trail 1 is 38.7 cm and in Trail 2 is 47.2 cm. Note that the longitudinal arch of the foot is well developed and resembles that of modern man, and the great toe is parallel to the other toes (Figs 7, 8 and 9).

Fossil record: two mandibles, parts of 2 maxillae, partial deciduous and permanent dentitions as well as a partial infant

skeleton and a number of isolated teeth have been recovered from the Laetolil Beds. They bear considerable resemblances to the material collected from the Afar in Ethiopia, although the Ethiopian material is substantially later.

Leporidae

Innumerable tracks of hares occur at all sites.

Fossil record: mandibles and other remains attributed to *Serengetilagus* sp. are abundant.

Carnivora

(1) Viverridae, indet. Series of small carnivore prints with non-retractile claws occur at all sites. They are generally lightly imprinted and rather faint. Average length/breadth 34 × 27 mm. Other small, rounded prints without claw marks, suggest genets. Average length/breadth 28 × 27 mm.

Fossil record: a variety of Viverridae are known among the fossils, some were described by Dietrich³, those from the recent collections are being studied by Mme G. Petter.

(2) Hyaenidae. Hyenas have left a series of well-defined and relatively long trails containing large numbers of prints. Eight trails are known and two gaits are represented. Subject to research on living hyaenas, these appear to be a walk and a slow canter or lope. There is uniformity in size, depth and stride within each of the four trails measured, although it is evident that the animals varied in individual size. Average length/breadth/depth measurements:

Trail C.22 (19 prints)	122 × 94 × 12 mm
Trail C.27 (30 prints)	125 × 102 × 22 mm
Trail C.31 (11 prints)	102 × 87 × 13 mm
Trail C.39 (18 prints)	111 × 100 × 18 mm

Fossil record: in a preliminary report, M. G. Leakey noted the existence of three species of hyena from the Laetolil Beds: (1) *Hyaena bellax* (Ewer 1954); (2) *Hyaenictis* cf. *preforlex* (Hendey 1974); and (3) *Lycyaena* sp.

(3) Felidae. One trail of 12 prints at site (A), and several isolated prints appear to correspond in size to those of a serval

Fig. 5 Print of cercopithecoid fore and hind foot at site C.

Fig. 6 Hominid footprints at site A.

cat. Average length/breadth/depth $65 \times 52 \times 13$ mm. Average length of stride 29 mm.

Fossil record: remains comparable to *F. serval* and *F. caracal* have been noted in the 1974–76 collections.

(4) *Machairodontinae*. Two prints at site (A), measuring 134×115 mm and 110×115 mm probably belong to a large sabre-tooth cat, as no other felid of comparable size occurs in the fossil material.

Fossil record: The presence of a large sabre-tooth cat, cf. *Homotherium* is indicated by two teeth.

Proboscidea

The proboscidean prints appear to belong to *Loxodonta exoptata* with the exception of one particularly well-preserved print in a trail of four at site (C) in which the phalanges and metapodials were more nearly vertical than in other known proboscidean prints and may be of a *Deinotherium*. The *Loxodonta* prints include a number made by juvenile animals as well as some that are usually large by present-day standards. The average for 15 measured prints, mostly adult, is $420 \times 346 \times 34$ mm.

Fossil record: both *Loxodonta exoptata* and *Deinotherium cf. bozasi* occur in the Laetolil Beds, but the latter is relatively scarce. A high proportion of the *Loxodonta* teeth are from juvenile animals.

Equidae

Only two equid trails are known. They have only recently been discovered and have not yet been fully studied. Both are at site (G), one on either side of the hominid trails but travelling in an opposite direction, to the south. The best preserved trail is 4.97 m long and contains 15 prints, nine of which can be measured. They range in length from 9.9 to 7.8 cm with an average of 8.6 cm and in width from 10.6 to 8.3 cm with an average of 8.8 cm. The animal appears to have changed gait during this trail.

Fossil record: numerous teeth, postcranial material and some incomplete mandibles have been found. All can be attributed to *Hipparion* sp.

Rhinocerotidae

Both *Ceratotherium* and *Diceros* must be represented among the many prints of rhinoceros, but no distinguishing features have been observed to date except on the basis of size. A trail at site (A) is one of the longest known, measuring 22 m in length. It contains 31 prints, 23 of which are double, with the hindfoot superimposed on the front. At the western end of the trail, where the animal changed gait, the prints become single and are irregularly spaced. Comparison with modern prints of *Diceros bicornis* at Olduvai show very close similarity. Average length/breadth/depth of double prints in trail: $416 \times 273 \times 31$ mm. Single prints, forefoot $246 \times 248 \times 25$ mm, hindfoot

$256 \times 228 \times 37$ mm. Isolated single fore and hind prints in the adjacent game trail are unusually large and may be of *Ceratotherium*. They measure $285 \times 310 \times 42$ mm and $400 \times 270 \times 33$ mm respectively.

Fossil record: on the basis of the early collections only *Ceratotherium* was believed to be present in the Laetoli fauna. But a skull of *Diceros* has now been found, as well as numerous teeth and some postcranial material.

Chalicotheriidae

Two Chalicotheres prints were found at site (C). They are deeply indented and measure $250 \times 155 \times 63$ mm and $243 \times 110 \times 46$ mm. The prints comprise impressions of three digits and of the palm. The digits have left symmetrical rounded grooves and the emplacement for a claw can be seen on one. The prints are 1.30 m apart.

Fossil record: a few specimens which can be referred to *Ancylotherium cf. hennigi* have been recovered. They include a calcaneum, astragalus and some phalanges.

Suidae

Thirteen suid prints at site (A) have been measured. They are comparable in size to prints of the living warthog. Average length/breadth/depth measurements are $55 \times 47 \times 11$ mm.

Fossil record: only two Suidae are known from the Laetolil Beds, *Potamochoerus* sp. and *Notochoerus euilus*. *Hylochoerus* and *Phacochoerus* were previously believed to be present in the early fauna, but during 1974–77 have only been found in the more recent deposits. On size, the prints are probably of *Potamochoerus*, as *Notochoerus* was a larger animal than the living warthog.

Giraffidae

(1) Three trails made by single animals are known. They consist of 6, 7 and 11 prints respectively. There are also 19 other prints attributed to giraffe. In one trail, the animal has dragged its feet after each step and left scuffed grooves up to 96 cm long. Average length/breadth/depth measurement for the prints in the trails are $190 \times 151 \times 29$ mm, $202 \times 144 \times 10$ mm, $211 \times 150 \times 17$ mm and $205 \times 150 \times 28$ mm. Averages for the isolated prints are $208 \times 155 \times 19$ mm.

Fossil record: the prints are of similar size to those of the modern giraffe and can be attributed to *G. jumae* which occurs as a fossil.

(2) Small giraffe cf. *G. stillei*. There are no prints which can positively be allocated to this animal, although its fossil remains are by far the most common giraffid. However, there are many prints, including three trails, which were identified as 'eland' by the tracker. No eland is known in the fossil fauna, nor is there any other bovid in the collection of a size suitable to have made these prints. For the present, it seems justifiable to assign these prints to the small giraffe. They are abundant at site (A), where there are three trails consisting of 21, 14 and 5 prints, as well as 72 isolated prints. The average length/breadth/depth measurements for the prints in the three trails are $140 \times 107 \times 14$ mm, $139 \times 104 \times 13$ mm and $128 \times 94 \times 16$ mm.

Fossil record: if the prints are correctly identified, they would belong to the animal originally named *Okapia stillei*, now known as *Giraffa stillei*.

(3) *Sivatherium*. No prints could be identified. The fossils consist mostly of isolated teeth and foot bones.

Bovidae

(1) Bovini cf. *Simatherium kohllarseni*. These prints consist of large, rounded and generally deeply indented tracks resembling those of the living African buffalo. They are clearly made by Bovini and can be attributed to *S. kohllarseni*, as this is the only bovine in the fossil record. The prints are represented by four trails containing 16, 12, 10 and 5 tracks, as well as 40 additional

Fig. 7 Dual trail of hominid footprints at site G.

Fig. 8 Outline of footprints shown in Fig. 7.

prints, either single or in pairs. The average length/breadth/depth measurements for the 43 prints in the trails are $185 \times 149 \times 25$ mm.

Fossil record: a number of horn cores and teeth have been found, including a cranium associated with both horn cores. (2) *Hippotragus* sp. Seven single prints from sites (A) and (C) were identified by the tracker as 'roan antelope'. They are characterised by widely splayed, elongate hoof-marks. The average length/breadth/depth measurements are $109 \times 95 \times 16$ mm.

Fossil record: three horn cores and some teeth, collected during 1975 are believed to be a hippotragine and have

Fig. 9 Left footprint of larger individual in dual trail at site G.

provisionally been attributed to *Praedamalis deturi*. A horn core and teeth in the earlier collections may also belong to this species which is smaller than the living roan antelope.

(3) Alcelaphini. Eighteen prints at site (A) and two at site (C) were identified by the tracker as hartebeest. The prints at site (A) are both smaller and shallower than those at site (C). Average length/breadth/depth for the former are $80 \times 60 \times 14$ mm and for the latter $103 \times 80 \times 23$ mm.

Fossil record: *Parmularius* sp. has been identified on a frontlet with horn cores, teeth and other fragmentary horn cores. There is also a cranium collected in 1959 which has been attributed to a larger species of alcelaphine. A third species may also be represented.

(4) Small antelopes and gazelles. Prints of dik-dik (*Madoqua*) are rare although dik-dik are the most abundant single species of fossil Bovidae. This anomaly may be explained by the fact that dik-dik are one of the Bovidae who do not require to drink

water, subsisting on moisture from vegetation, while tracks of other Bovidae were probably made going to or from water holes.

Fossil record: *Neotragini*? and *Raphicerus* sp. (Steenbuck) are provisionally identified. *Madoqua* is very abundant. *Antilopini*: the gazelle appears to be *G. janenschii*.

Conclusions

The greater part of the fossil fauna from the Laetoli Beds is recorded in the fossil tracks. In all, over 20 taxa are represented. The preservation of the footprints can be attributed to an unusual and possibly unique combination of climatic, volcanic and mineralogic conditions. The available evidence indicates that the episode took place during a brief period, probably during the onset of a single rainy season which happened to coincide with the eruption of light ash showers from the nearby volcano Sadiman.

The locomotor pattern displayed by the trails of hominid footprints is still under examination but it is immediately evident that the Pliocene hominids at Laetoli had achieved a fully upright, bipedal and free-striding gait; a major event in the evolution of man which freed the hands for tool-making and eventually led to more sophisticated human activities. Moreover, evidence supplied by cranial parts of the somewhat later but related hominid fossils from the Afar in Ethiopia (dated between 2.6 and 3 Myr) indicates that bipedalism outstripped

enlargement of the brain. To have resolved this issue is an important step in the study of human evolution, as it has long been the subject of speculation and debate.

With the hands free and available for purposes not connected with locomotion it is perhaps surprising that no form of artefact has been found. But the concept of tool-making may well have been beyond the mental ability of these small-brained creatures. Any 'tools' or weapons used must have been solely of perishable materials as the Laetoli Beds are devoid not only of artefacts but of all stones other than volcanic ejecta.

Further exploration of sites and analysis of material will continue in 1979, but it is evident that Laetoli will give an unique perspective into hominid environment during Pliocene times.

We thank the United Republic of Tanzania for permission to continue research at Laetoli, the National Geographic Society, Washington, D.C. for financial support, A. A. Mturi, Director of Antiquities, Tanzania and A. J. F. Mgina, Conservator, Ngorongoro Conservation Authority, for their help, Philip Leakey and Peter Jones for organising field seasons, Drs A. W. Gentry, J. Harris and M. G. Leakey for identifying the bovid, giraffid, primate and carnivore fossils and all those who participated in the fieldwork.

Department of Cell Biology and the Howard Hughes Medical Institute Laboratory at Baylor College of Medicine, Houston, Texas 77030

A 15-kilobase pair EcoRI chick DNA fragment, containing both the termination codon UGA and the 5'-portion of the structural ovomucoid gene, has been cloned in λ phage Charon 4A by in vitro packaging. Restriction mapping and electron microscopic analyses of this cloned DNA have revealed that the structural ovomucoid gene sequences are separated by at least six intervening sequences.

OVOMUCOID is a major egg-white protein, and its synthesis in the chick oviduct is regulated by the steroid hormones oestrogen and progesterone¹⁻³. Using a specific hybridisation probe comprised of a complementary DNA synthesised from purified ovomucoid messenger RNA, it has been demonstrated that the steroid-mediated induction of ovomucoid synthesis in the chick oviduct is preceded by the accumulation of its messenger RNA⁴. We have recently succeeded in the isolation and amplification of the structural ovomucoid gene by molecular cloning⁵. Using the cloned ovomucoid DNA as a specific hybridisation probe, we have shown that the kinetics of hormonal induction of ovomucoid mRNA accumulation in the chick oviduct is similar to that of ovalbumin mRNA⁶⁻⁹. To study the mechanisms by which steroid hormones regulate the expression of these oviduct genes, we attempted to define their sequence organisation within genomic chick DNA. We have recently reported the cloning of various *EcoRI* fragments of the natural ovalbumin

gene¹⁰⁻¹³. Detailed analysis of these cloned DNA fragments have shown that the structural ovalbumin gene is separated into at least eight portions by seven intervening sequences^{11,13,14}. The discovery of intervening sequences within eukaryotic genes has introduced a new level of complexity in the elucidation of the mechanism of gene expression. To substantiate the pattern for genetic organisation, we have attempted to clone the natural ovomucoid gene so that we might establish the sequence organisation of this gene.

The recombinant plasmid pOM100

Ovomucoid complementary DNA (cDNA_{om}) was previously synthesised from a partially purified ovomucoid mRNA preparation and cloned in the *PstI* site of pBR322 (ref. 5). Several recombinant clones have been demonstrated to contain inserted ovomucoid cDNA sequences by direct DNA sequencing. One of these recombinant plasmids, designated pOM100, contains about 650 base pairs of DNA, including the 3'-portion of the mRNA, and lacks about 125 base pairs at the 5'-terminus of the structural ovomucoid gene. A preliminary structure of the cloned ovomucoid cDNA (Fig. 1) has been established by restriction mapping⁵ and DNA sequencing (J.F.C., unpublished). It contains a *KpnI* site very close to the 5'-end of the inserted DNA. There is a unique *HincII* site and two cleavage sites each for *PstI* and *HaeIII* within the peptide coding portion of the gene. The ovomucoid structural gene also contains 138 base pairs of untranslated region at the 3'-terminus following the termination codon and there are unique *EcoRI* and *BamHI* sites

Fig. 1 Structure of pOM100 and the preparation of ovomucoid DNA fragments as specific hybridisation probes. □, Ovomuroid DNA insert; —, pBR322 DNA; wavy, dA-dT linkers. The various restriction endonuclease sites of the ovomucoid DNA insert are as indicated by the arrows. The numbers in parentheses indicate the size of the fragments in kilobases. 300 µg of pOM100 DNA was digested with *HhaI* (BRL) in standard conditions. The digestion products were separated by electrophoresis in a 1% preparative agarose gel. The 1.04-kilobase fragment (OM_T) was recovered from the gel by diffusion as described previously³⁶ and was further digested with *HincII* into two fragments of 0.63 (OM_L) and 0.41 (OM_R) kilobases, respectively. These fragments were again isolated by preparative gel electrophoresis. OM_T, OM_L and OM_R were labelled with [α -³²P]dCTP by nick translation to a specific radioactivity of about 2×10^8 c.p.m. per µg (ref. 15).

located in this region. The cloned ovomucoid DNA is not cleaved by the restriction enzymes *HhaI*, *HindIII*, *AvaI* or *TaqI*.

As the cloned ovomucoid DNA does not contain any *HhaI* cleavage site, a DNA fragment containing the entire inserted DNA fragment was prepared by *HhaI* digestion of pOM100 followed by preparative agarose gel electrophoresis (Fig. 1). This 1.04-kilobase DNA fragment (OM_T) was further digested with *HincII* into two DNA fragments containing the left (OM_L) and right (OM_R) halves of the cloned ovomucoid DNA. These DNA fragments were again separated from each other by preparative agarose gel electrophoresis and used as specific hybridisation probes after labelling by nick translation¹⁵.

Identification of chick DNA fragments containing the ovomucoid gene

Total chick DNA was digested with *EcoRI* and subjected to agarose gel electrophoresis. A large number of DNA fragments, heterogenous in size, can be visualised as a broad banding pattern in the gel after staining with ethidium bromide (Fig. 2A, lane a). The DNA fragments in the gel were transferred onto a nitrocellulose filter by the method of Southern¹⁶. The filter was treated according to the procedure of Denhardt¹⁷, and those DNA fragments on the filter containing structural ovomucoid gene sequences were identified by hybridisation with ³²P-OM_T followed by autoradiography¹⁸ (Fig. 2B, lane a). It is evident from this experiment that the structural ovomucoid gene sequences are contained within two *EcoRI* DNA fragments of 15 and 7 kilobases. The separation of the structural gene sequences into two *EcoRI* DNA fragments was not unexpected, as there is an *EcoRI* cleavage site within the structural gene. The order of these two DNA fragments was established by hybridising total *EcoRI*-digested DNA with OM_L and OM_R separately. The 15-kilobase DNA fragment hybridised with both probes, whereas the 7-kilobase DNA fragment hybridised with OM_R only (data not shown). Thus, the 15-kilobase DNA fragment contains the 5'-portion of the ovomucoid gene.

Cloning of the natural ovomucoid gene

The 15-kilobase DNA fragment was enriched from total *EcoRI*-digested chick DNA by preparative agarose gel electrophoresis. The gel was cut into 3-mm slices and DNA recovered from each gel slice was assayed for ovomucoid gene content by analytical gel electrophoresis followed by Southern hybridisation using

³²P-OM_T. The ethidium bromide staining pattern and autoradiogram of these individual DNA fractions are shown in lanes b-e of Fig. 2A and B, respectively. It is evident that the DNA fraction displayed in lane c is enriched for the 15-kilobase ovomucoid DNA fragment. This DNA fraction was thus used to clone the ovomucoid gene.

λ Phage Charon 4A contains three *EcoRI* cleavage sites and yields four DNA fragments on digestion with *EcoRI* (Fig. 2A, lane f). The two upper phage DNA arms were separated from the middle *EcoRI* DNA fragments by preparative agarose gel electrophoresis, and allowed to ligate in the presence of the DNA fraction enriched for ovomucoid DNA using T4 DNA ligase. The ligation mixture was used for cloning in a P3 facility by *in vitro* packaging according to the method of Sternberg *et al.*¹⁹ as modified by Faber, Kiefer and Blattner (personal communication). Briefly, λ lysogens were induced and cell extracts were made by alternate freezing and thawing and by sonication. The two protein extracts were mixed with purified λ A protein and incubated at 37 °C for 60 min and 5 µl of the ligation mixture in a final volume of 0.25 ml. The packaging mixture was plated in 12-µl aliquots in soft agar on 20 agar plates. Approximately 20,000 phage plaques were generated in this experiment. These phages were screened for the recombinant phage containing the ovomucoid gene by hybridisation with the OM_T probe using an amplification procedure as described previously¹⁰. Three phage plaques gave positive signals on the autoradiograms in this test. These phages were cultured individually and their DNA prepared. *EcoRI* digestion of DNA from any of the three phages produced two DNA fragments corresponding to the arms of Charon 4A and an additional 15-kilobase DNA fragment (Fig. 2A, lane g), which hybridised with the ovomucoid structural sequence OM_T on Southern analysis (Fig. 2B, lane g). This 15-kilobase DNA fragment of the natural ovomucoid gene was subsequently recloned in pBR322 in *Escherichia coli* χ 1776 and was designated pOM15.

Restriction mapping of the cloned 15-kilobase ovomucoid DNA

The 15-kilobase ovomucoid DNA (OM15) was excised from pBR322 DNA by *EcoRI* digestion of the recombinant plasmid pOM15 followed by preparative agarose gel electrophoresis. The excised ovomucoid DNA was further digested with a variety of other restriction endonucleases and those DNA fragments containing the left and right halves of the structural ovomucoid

Fig. 2 Agarose gel electrophoresis of various DNA fractions and identification of ovomucoid DNA sequences by Southern¹⁶ hybridisation. A Shows the ethidium bromide stain of the gel and B the corresponding autoradiogram after the DNA was transferred from the gel to a nitrocellulose filter and hybridised to ³²P-OM_T. Lane M: 1 µg of *EcoRI*-digested wild-type λ phage DNA; lane a: 15 µg of *EcoRI*-digested total chick DNA; lanes b-e: 1.0 µg each of *EcoRI*-digested chick DNA extracted from various gel slices of a preparative gel; lane f: 0.5 µg of the *EcoRI*-digested Charon 4A λ DNA; lane g: *EcoRI*-digested DNA from one of the three recombinant phages that hybridised with ³²P-OM_T.

Fig. 3 Autoradiogram of 1% agarose gel containing OM15 DNA after digestion with various restriction endonucleases and Southern hybridisation. OM15 DNA was extracted from *EcoRI*-digested pOM15 by preparative agarose gel electrophoresis. 100 ng of purified OM15 DNA were digested by respective restriction endonucleases as indicated above each lane in the autoradiogram. Electrophoresis was carried out in 1% agarose gels and DNA was transferred to nitrocellulose. Hybridisation was carried out with ^{32}P -labelled OM_L (left panel) and ^{32}P -labelled OM_R (right panel), respectively.

gene sequences were identified by agarose gel electrophoresis followed by Southern hybridisation with the OM_L and OM_R probes, respectively. Some of the data are shown in Fig. 3 and summarised in Table 1. These data were used to construct a preliminary map of the natural ovomucoid gene as shown in Fig. 4. As expected, the OM15 DNA hybridised with both probes (Fig. 3). *HincII* digestion of OM15 DNA resulted in two DNA fragments of 8.0 and 1.1 kilobases that hybridised with OM_L and a unique 0.7-kilobase DNA fragment that hybridised with OM_R but not OM_L (Fig. 3). Thus, there is a *HincII* site (*HincII*_c) 0.7 kilobases to the left of the *EcoRI*_b site (Fig. 4). By virtue of the method used to prepare the two probes, the *HincII*_c site must be the unique *HincII* cleavage site present in the structural ovomucoid gene (Fig. 1). Limited sequence analysis has also established that the *EcoRI*_b site is the one present in the struc-

tural ovomucoid gene (data not shown). The unique *HincII* and *EcoRI* sites in the structural gene, however, are separated by only 0.2 kilobases of DNA. Thus, it seems that these two sites may be separated by an intervening sequence in genomic DNA. Furthermore, there should be a *HincII* site (*HincII*_a) 9.1 kilobases to the left of *HincII*_c. The *HincII*_b site, however, could be either 8.0 or 1.1 kilobases to the left of the *HincII*_c.

BamHI digested the OM15 DNA into a 10-kilobase DNA fragment hybridisable with both OM_L and OM_R (Fig. 3). In addition, there is a 0.3-kilobase fragment hybridisable only with OM_R, and resistant to *HincII* digestion (Table 1). Thus, there should be a *BamHI* site (*BamHI*_b) 0.3 kilobases to the left of *EcoRI*_b, and an additional *BamHI* site (*BamHI*_a) 10 kilobases to the left of *BamHI*_b (Fig. 4). The presence of these two *BamHI* sites predicts that a *HincII* digestion of the *BamHI* DNA fragments would result in a 8.0 and a 1.1 kilobase DNA fragment that would hybridise with OM_L only, and that the 0.7-kilobase *HincII* DNA fragment would be digested by *BamHI* into two fragments of 0.4 and 0.3 kilobases, respectively. These are exactly the results observed (Table 1). As there is no *BamHI* cleavage site between the *HincII* and *EcoRI* sites in the structural gene, these results confirm that there must be at least one intervening sequence separating these two restriction sites in the structural ovomucoid gene.

HindIII digested OM15 DNA into a 3.5-kilobase DNA fragment hybridisable with both OM_L and OM_R probes, as well as a 0.9-kilobase DNA that hybridised with OM_L only (Fig. 3). Thus, there should be a *HindIII* site (*HindIII*_b) 3.5 kilobases to the left of *EcoRI*_b, and an additional *HindIII* site (*HindIII*_a) 0.9 kilobases to the left of *HindIII*_b (Fig. 4). Indeed, the 3.5-kilobase DNA is cleaved by *HincII* into a 1.1 and a 0.7 kilobase fragment hybridisable with OM_L and OM_R, respectively, which are the same DNA fragments observed by digestion of OM15 DNA with *HincII* alone (Table 1). This experiment further suggests that the *HincII*_b site is 1.1 kilobases to the left of *HincII*_c and that there is no structural gene sequence between *HindIII*_b and *HincII*_b. In addition, there should be some structural gene sequence within the 0.9-kilobase *HindIII* DNA fragment (Fig. 4). The fact that the structural gene contains no *HindIII* cleavage site suggests that there may be more intervening DNA sequences within the natural ovomucoid gene.

KpnI digested the OM15 DNA into a 3.7-kilobase fragment hybridisable with both OM_L and OM_R and an additional 8.5-kilobase DNA fragment hybridisable only with OM_L (Fig. 3). Hence, there should be a *KpnI* site (*KpnI*_b) 3.7 kilobases to the left of *EcoRI*_b, and another *KpnI* site (*KpnI*_a) 8.5 kilobases to the

Fig. 4 Structural organisation of the natural ovomucoid gene (OM15). Ovomucoid structural sequences are represented by $\square$, intervening sequences by $\blacksquare$, and flanking DNA sequences by — . The arrows indicate various restriction endonuclease sites on the ovomucoid gene. Those above the schematic drawing indicate restriction sites present in the structural ovomucoid gene and those below are sites within the intervening or flanking DNA sequences. There are additional restriction sites present in the left-hand portions of OM15 DNA, but their positions have not been mapped and are therefore not shown.

Table 1 Sizes of ovomucoid structural sequence-containing fragments after restriction endonuclease digestion of OM15

	Size after digestion (kilobases)								Probe used
	<i>EcoRI</i>	<i>HindIII</i>	<i>BamHI</i>	<i>TaqI</i>	<i>AvaI</i>	<i>KpnI</i>	<i>HaeIII</i>	<i>PstI</i>	
- <i>HincII</i>	15.0	3.5	10.0	2.4	3.5	8.5	1.0	0.75	OM _L
		0.9			2.3	3.7	0.5	0.75	
+ <i>HincII</i>	8.0	1.1	8.0	1.1	2.3	6.0	0.6	0.7	OM _L
	1.1	0.9	1.1		1.1	1.1	0.5	0.3	
- <i>HincII</i>	15.0	3.5	10.0	0.75	3.5	3.7	0.7	0.65	OM _R
			0.3						
+ <i>HincII</i>	0.7	0.7	0.4	0.7	0.7	0.7	0.7	0.65	OM _R
			0.3						

left of *KpnI*_b. Double digestion of OM15 DNA with *KpnI* and *HincII* yielded a 0.7-kilobase fragment hybridisable with OM_R as expected, as well as two DNA fragments of 6.0 and 1.1 kilobases that hybridised with OM_L as predicted from the map (Fig. 4). Thus, the *KpnI*_b site seems to be the one that is present towards the 5'-terminus of the structural ovomucoid gene (Fig. 1). Because this *KpnI* site is separated from the *HincII*_c site by a *HindIII* site in genomic DNA but not in the structural gene, there should be a second intervening sequence separating these sites in the natural ovomucoid gene.

The OM15 DNA was digested by *HaeIII* into a unique 0.7-kilobase DNA fragment hybridisable with OM_R and resistant to *HincII* digestion (Table 1). Hence, there is a *HaeIII* site (*HaeIII*_c) about 0.7 kilobases to the left of *EcoRI*_b, which could be one of the two *HaeIII* sites located near the unique *HincII* site in the structural gene (Fig. 1). As there are two *HaeIII* fragments of 1.0 and 0.5 kilobase that hybridised with OM_L, there should be a *HaeIII* site (*HaeIII*_a) 1.5 kilobases to the left of *HaeIII*_c. Furthermore, the 0.5-kilobase *HaeIII* fragment seem to be resistant to *HincII*, whereas the 1.0-kilobase fragment is cleaved by this enzyme to a 0.6-kilobase fragment hybridisable with OM_L (Table 1). Thus, the *HaeIII*_b site should be located 0.5 kilobases to the left of *HaeIII*_c. Otherwise, the 1.0-kilobase *HaeIII* DNA fragment would be resistant to *HincII* and the 0.5-kilobase fragment would be digested to a 0.4- and a 0.1-kilobase fragment. Furthermore, this *HaeIII*_b site may be the second *HaeIII* site present in the structural gene (Fig. 1), as both the 0.5- and 1.0-kilobase *HaeIII* DNA fragments hybridised with OM_L. By similar analysis, a *TaqI* site (*TaqI*_b) has been located between the *HaeIII*_b and *HaeIII*_c sites (Fig. 4). As the *HaeIII* sites in the structural gene are not separated by a *TaqI* site, there may be a third intervening sequence within the ovomucoid gene.

PstI digested the OM15 DNA into a unique 0.65-kilobase fragment hybridisable with OM_R, and resistant to further digestion by *HincII* (Table 1). Hence, a *PstI* site (*PstI*_c) should be located 0.65 kilobases to the left of *EcoRI*_b and could be the *PstI* site located 0.05 kilobases to the right of the unique *HincII* site present in the structural gene (Fig. 1). Although *PstI* digestion yielded only one 0.75-kilobase band when hybridised with OM_L (Table 1), there must be at least two DNA fragments of the same size because one of the fragments was digested by *HincII* into a 0.3-kilobase fragment and the other fragment remained resistant. Hence, there should be two *PstI* sites, 0.75 kilobases apart, to the left of *PstI*_c. Moreover, the *PstI*_b site may be the other *PstI* present in the structural gene (Fig. 1), because the 0.75-kilobase *PstI* fragment would have been digested to one of 0.45 kilobases instead of a 0.3-kilobase fragment if *PstI*_a were the site present in the structural gene instead. The finding that the *PstI*_b and *HaeIII*_b sites are separated by 0.3 kilobases in genomic DNA but by only about 0.07 kilobases in the structural gene (Fig. 1), suggests that there may be a fourth intervening sequence within the ovomucoid gene.

These results indicate that the structural ovomucoid gene sequences are not contiguous and are apparently separated into several portions by multiple intervening sequences within the chick genome. The existence of four intervening sequences as established by limited restriction analyses of the cloned OM15

DNA should be a minimum estimation of the number of intervening sequences.

Electron microscopic mapping of the ovomucoid gene

Although intervening sequences within structural genes can be detected by restriction enzyme mapping, a complete map requires other methods independent of the chance occurrence of restriction sites. Short structural gene regions may be missed due to the relative instability of the hybrids formed during hybridisation, resulting in weak signals on Southern filter analysis. In an attempt to characterise the structure of the ovomucoid gene more fully, hybrid molecules formed between ovomucoid mRNA and the cloned 15-kilobase ovomucoid DNA were examined by electron microscopy.

DNA was thermally denatured and incubated with ovomucoid mRNA in conditions that permit only RNA:DNA hybridisation but not DNA:DNA reassociation. Thus, homologous regions between the mRNA and the cloned DNA would appear as double-stranded structures and between the double-stranded regions, DNA sequences non-homologous with the mRNA would appear as single-stranded loops. Figure 5 shows such a hybrid molecule formed between ovomucoid mRNA and the cloned OM15 DNA. Six intervening DNA loops of various sizes are apparent in this molecule, all of which were present in 10 individual hybrid molecules examined. The relative positioning of these loops was established in a histogram as shown in Fig. 6. All the loop structures occurred at one DNA

Fig. 5 Electron micrograph and line drawing of a hybrid molecule formed between the ovomucoid gene (OM15) and ovomucoid mRNA. Hybridisation was carried out using 10 $\mu\text{g ml}^{-1}$ of OM15 DNA and 20 $\mu\text{g ml}^{-1}$ of ovomucoid mRNA in 70% deionised formamide containing 100 mM Tris-HCl, pH 7.6, 10 mM sodium EDTA and 150 mM NaCl. The mixture was heated at 80 °C for 5 min to denature the DNA and hybridisation was carried out at 43 °C for 2 h. The samples were immediately prepared for electron microscopy as follows. The hybridisation mixture containing 0.1–0.5 μg of nucleic acids was diluted into 100 μl of a solution containing 70% formamide, 0.1 M Tris-HCl, pH 8.4, 0.01 M sodium EDTA and 100 $\mu\text{g ml}^{-1}$ of cytochrome *c*. The mixture was spread onto a hypophase of distilled water. Samples were collected on collodion-coated 300-mesh copper grids, stained with uranyl acetate, rotary shadowed with platinum-palladium, and examined at 80 kV on a Joel 100 C electron microscope. —, OM15 DNA; ----, mRNA_{om}.

terminus and occupied about one-third of the total length of the OM15 DNA molecule. This observation agrees with the restriction map as shown in Fig. 4. Two additional intervening sequences were detected in these studies. The short intervening sequences C and F were not detected by restriction mapping analysis.

Comments

We have reported the cloning of the chick ovomucoid gene in λ phage Charon 4A by *in vitro* packaging. The great efficiency of *in vitro* packaging has enabled us to limit purification of the gene to approximately 10-fold by preparative agarose gel electrophoresis and only nanogram quantities of DNA are required. *In vitro* packaging thus makes it possible to eliminate laborious DNA enrichment procedures before cloning.

Four intervening sequences were detected in the ovomucoid gene by limited restriction enzyme mapping. Electron microscopic analysis of RNA:DNA hybrids between ovomucoid mRNA and the 15-kilobase cloned ovomucoid gene fragment showed six loops corresponding to intervening sequences. Both methods have advantages in locating intervening sequences. Restriction mapping is more quantitative in that fragment sizes

Fig. 6 Histogram of 10 individual hybrid molecules formed between OM15 DNA and ovomucoid mRNA in conditions described in the legend to Fig. 5. The molecules were measured using a map measure, and the sizes and positions of the loops were plotted on a linear scale of 0 to 1, with 1.0 representing 15 kilobases of DNA. Ovomucoid structural sequences are represented by $\square$, intervening sequences by $\blacksquare$, and flanking DNA sequences by —.

and position can be correlated with known distances in the structural sequence. However, in the absence of favourably placed restriction sites, some intervening sequences may be missed. Electron microscopy permits more direct analysis of intervening sequences; in our studies, it has detected two additional intervening sequences, but the overall structure was in good qualitative agreement with the limited restriction map.

There are at least six intervening sequences in the ovomucoid gene. This is, necessarily, a minimum number; nucleotide sequence data are required for a complete structural charac-

terisation. A short structural sequence at the 5'-end may not form a stable hybrid in the conditions used. A 5.5-kilobase potential RNA precursor has been detected in nuclei from stimulated oviducts (see accompanying paper²⁰). Preliminary RNA-excess hybridisation experiments with fragments of the cloned gene have indicated that an additional 1.5 kilobases of DNA to the left of the unique *Kpn*I site may be transcribed *in vivo*. These observations suggest that the difference in size between the gene (Fig. 4) and the high molecular weight RNA transcript may be due to an undetected intervening sequence at the 5'-end. The size of the ovomucoid gene then, including the structural sequence beyond the *Eco*RI site, is about 5.5 kilobases, which is in good agreement with the estimated size of the largest RNA precursor. As the *Eco*RI site in the structural gene is a few nucleotide pairs to the right of the termination codon, all six intervening sequences observed in OM15 DNA are situated within the peptide-coding portion of the ovomucoid gene.

Although intervening sequences have been observed in several other cloned eukaryotic genes^{10-14,21-29}, the frequency of occurrence of these sequences in the ovomucoid gene is striking. Even in the absence of additional intervening sequences in the 3'-untranslated region, there is a minimum of six such sequences within a structural gene only about 750 nucleotide pairs long. At 1 intervening sequence per 125 nucleotide pairs of structural gene sequence, it represents the highest frequency of intervening sequences observed among all eukaryotic genes examined to date.

With regard to the expression of the ovomucoid gene *in vivo*, the entire gene is apparently transcribed into a large RNA transcript which is subsequently spliced to yield the mature mRNA. The identification of high molecular weight ovomucoid RNA precursors by methylmercury hydroxide agarose gel electrophoresis followed by transfer of RNA to diazobenzyloxymethyl paper and hybridisation with labelled pOM100 is presented in the accompanying paper²⁰. In this regard, the ovomucoid gene is similar to other genes with intervening sequences, such as those coding for chick ovalbumin³⁰, mouse globins³¹, mRNAs of animal viruses^{32,33} and yeast tRNAs^{34,35}. Finally, studies of the structures and the expression of the ovalbumin and ovomucoid genes should further our understanding of the regulation of these chick oviduct genes.

We thank Dr Frederick Blattner for providing us with the Charon 4A host-vector system and the protocol for *in vitro* packaging, and Mr Lawrence Day, Ms Yvonne Hodges and Sulaf Skory for technical assistance. The work was supported by NIH grants HD-08188 and HD-C7495 (Baylor Center for Population Research and Reproductive Biology), American Cancer Society grant BC-101 and a Robert A. Welch Foundation grant Q-611. S.L.C.W. is an Associate Investigator of the Howard Hughes Medical Institute.

Note added in proof: Further electronmicroscopic mapping of the gene has indicated that there is a seventh intervening sequence. A short structural gene segment has been detected in intervening sequence A.

Identification of potential ovomucoid mRNA precursors in chick oviduct nuclei

Jeffrey L. Nordstrom, Dennis R. Roop, Ming-Jer Tsai & Bert W. O'Malley

Baylor College of Medicine, Department of Cell Biology, Houston, Texas 77030

Denaturing gel electrophoresis of chick oviduct nuclear RNA reveals multiple species of RNA that are 1.5–5 times larger than ovomucoid mRNA. By analogy with ovalbumin RNA processing, these data suggest that ovomucoid mRNA is derived from a primary transcript that contains intervening sequences.

ADMINISTRATION of oestrogen to immature chicks induces the accumulation of the mRNAs for the egg-white proteins ovalbumin^{1–7}, ovomucoid^{8,9}, conalbumin¹⁰ and lysozyme⁸ in oviduct target cells. Of these four mRNAs, that of ovalbumin is the most abundant and has therefore been most extensively studied. Several lines of evidence^{7,11,12} suggest that ovalbumin mRNA (mRNA_{ov}) is derived from a large nuclear precursor RNA which is a transcript of the chick ovalbumin gene which is interrupted by at least seven regions of intervening sequence DNA^{13,14}. RNA sequences complementary to the intervening sequence regions were detected in oviduct nuclei⁷, but not in oviduct polysomes¹¹, indicating that they are not transported from the nucleus. In addition, multiple species of nuclear RNA larger than ovalbumin mRNA have been fractionated by gel electrophoresis and have been shown to contain both ovalbumin structural and intervening sequences⁷. We report here that there are also multiple species of nuclear RNA larger than the mRNA for ovomucoid. The experiments have been made possible because we have recently cloned complementary DNA (cDNA) to ovomucoid mRNA (mRNA_{om}) and prepared a DNA fragment that contains the cDNA sequence¹⁵. Using this specific probe, we have analysed the distribution of ovomucoid mRNA sequences in oviduct nuclear RNA that has been fractionated by agarose gel electrophoresis in completely denaturing conditions.

Identification of multiple nuclear species of ovomucoid sequence-containing RNA

To search for species of ovomucoid RNA larger than mature mRNA_{om}, nuclear RNA from oviducts of oestrogen-stimulated chicks was subjected to agarose gel electrophoresis in the presence of the denaturing agent, methylmercury hydroxide. Following transfer of the RNA from the gel onto diazobenzyloxymethyl (DBM) paper and hybridisation to a ³²P-labelled ovomucoid cDNA probe, multiple discrete bands containing ovomucoid structural sequences were observed (Fig. 1, lane A). The band with the greatest mobility co-migrated with mature mRNA_{om} (Fig. 1, lane B). Five major bands were significantly larger than ovomucoid mRNA (1,100 nucleotides). In addition, two minor bands were detected in certain nuclear RNA preparations (Fig. 2, lane C). As shown in Table 1, the sizes of the seven species of high molecular weight (MW) ovomucoid RNA, which were labelled a–g, ranged from 1.5 to 5 times the size of ovomucoid mRNA. The mobilities of the prominent ovomucoid RNAs (bands a, b, d, e, g) were reproducibly observed in all preparations of oviduct nuclear RNA that were analysed. Based on its intensity, band g, which has 1,700 nucleotides, seems to be the most abundant species of high MW ovomucoid RNA. Based on the radioactivity associated with each band, as determined by liquid scintillation counting, we estimate that 20–45% of the nuclear ovomucoid sequences reside in the forms higher in MW than mRNA_{om}.

High MW species of RNA that contain ovomucoid sequences were not found in oviduct cytoplasm, where only mature mRNA_{om} was detected (Fig. 1, lane C). In addition, the presence of nuclear high MW ovomucoid RNA, as well as that of mature mRNA_{om}, was tissue specific. No ovomucoid bands were detected in the nuclear RNA from spleen or liver that was isolated from oestrogen-stimulated chicks (Fig. 1, lanes D, E). Thus, high MW ovomucoid RNA, as well as mRNA_{om}, is present in significant amounts only in those tissues that actively synthesise egg-white proteins.

Although the conditions used for electrophoresis were rigorously denaturing^{7,18}, an attempt was made to generate high MW species of ovomucoid RNA by mixing liver nuclei and oviduct cytoplasm (both prepared from chicks stimulated with diethylstilboestrol (DES)) and then extracting the RNA from the mixture. However, mRNA_{om} was the only species detected (Fig. 1, lane F). Thus, as was observed previously for ovalbumin RNA⁷, the high MW species of ovomucoid RNA do not seem to be due to aggregation of mRNA_{om} with itself or other RNA molecules.

Comparison of the nuclear species of ovalbumin and ovomucoid RNA

To permit an exact comparison of the bands of high MW ovalbumin and ovomucoid RNA, oviduct nuclear RNA that had been electrophoresed and transferred to DBM paper was first hybridised to a ³²P-labelled probe specific for ovalbumin RNA sequences (Fig. 2, lane A). Following autoradiography, the ³²P-ovalbumin probe was eluted (Fig. 2, lane B) and the same DBM paper rehybridised, except this time to the ³²P-ovomucoid probe (Fig. 2, lane C). Two of the species of ovalbumin RNA (Fig. 2a,b) had significantly higher MWs than the largest species of ovomucoid RNA. Of all the bands observed, only ovalbumin RNA f and ovomucoid RNA b shared the same electrophoretic mobility. As the intensity of the bands differed, however, it is unlikely that they represent the same species of RNA. Thus, ovalbumin and ovomucoid RNA do not seem to have any of the high MW species in common.

Table 1 Sizes of the ovomucoid sequence-containing RNA from chick oviduct nuclei

RNA _{om} species	Relative mobility (to mRNA _{om})	Length (nucleotides)
a	0.25	5450 ± 120
b	0.45	3100 ± 60
c	0.48	2750 ± 60
d	0.55	2500 ± 60
e	0.59	2300 ± 50
f	0.65	2000 ± 30
g	0.76	1700 ± 75
mRNA _{om}	1.0	1100 ± 110

Relative mobility was calculated as the average of 6 individual experiments. Length was calculated by comparison with the electrophoretic mobility of RNA and DNA standards. RNA standards were chicken 27S rRNA (4,530 nucleotides), chicken 18S rRNA (2,076 nucleotides), *Escherichia coli* 23S rRNA (3,129 nucleotides) and *E. coli* 16S rRNA (1,550 nucleotides). DNA standards were obtained by digestion of λ DNA with *EcoRI* (21,746, 7,524, 5,920, 5,523, 4,793 and 3,380 nucleotides) or with *HindIII* (23,222, 9,730, 6,460, 4,492, 2,301, 2,000 and 682 nucleotides). In the conditions of electrophoresis (in the presence of methylmercury hydroxide), DNA becomes single stranded and its mobility is similar to that of RNA. Error limits indicate the standard deviation.

Based on the relative intensities of the bands, the concentration of ovalbumin mRNA, as expected, is greater than that of ovomucoid mRNA. By contrast, the high MW species of ovomucoid RNA are apparently more abundant in oviduct nuclei than the high MW species of ovalbumin RNA. It is of further interest that a significant portion of the nuclear ovalbumin RNA sequences was smaller than mRNA_{om}. By contrast, no significant degradation of mRNA_{om} was observed.

Identification of ovomucoid intervening sequences in high MW nuclear RNA

Restriction endonuclease mapping and electron microscopic analysis of a cloned DNA fragment reveal that, like the ovalbumin gene, the natural chick ovomucoid gene has at least six regions of intervening sequence¹⁹. Using as a hybridisation probe a clone with a DNA insert that seems to contain all the ovomucoid structural and intervening sequences, it has been possible to determine that the nuclear ovomucoid RNA molecules larger than the mature mRNA_{om} contain sequences complementary to the intervening sequences of the ovomucoid gene. Apart from band *f*, all the bands of ovomucoid nuclear RNA, including mature mRNA_{om}, that hybridised to the ovomucoid cDNA probe were again detected when hybridised to the natural ovomucoid gene probe (Fig. 3, lane A). In addition, two bands (located between bands *a* and *b*) that were extremely faint after hybridisation to the ovomucoid cDNA probe were clearly detected by the natural ovomucoid gene probe. To detect only those bands that contained intervening sequences, it was necessary to hybridise in the presence of excess unlabelled ovomucoid mRNA to compete out the structural sequences in the natural gene. In these hybridisation conditions, detection of the band corresponding to mature mRNA_{om} was eliminated (Fig. 3, lane B). In contrast, all the bands of high MW ovomucoid RNA were still detected. This indicates that all the species of ovomucoid RNA larger than mature mRNA_{om} contain sequences complementary to the intervening sequences of the ovomucoid gene.

Oestrogen-induced accumulation of high MW species of ovomucoid RNA

The accumulation in the oviduct nucleus of species of ovomucoid RNA larger than mature mRNA_{om} was dependent on oestrogen. From 20 µg of oviduct nuclear RNA isolated from chicks that had been withdrawn from DES treatment for 14 d, neither high MW ovomucoid RNA nor mRNA_{om} was detected (Fig. 4, left, lane W). Thus, in agreement with our previous studies using *R₀* analysis⁹, the amount of ovomucoid RNA sequences in withdrawn oviduct nuclei is very low. When 100 µg of withdrawn oviduct nuclear RNA was analysed, a faint band of mRNA_{om} was observed (Fig. 4, right, lane W). Thus, the few ovomucoid RNA sequences that remain after hormone withdrawal seem to be present mainly in the form of mature mRNA_{om}.

As soon as 1 h after administration of DES to hormone-withdrawn chicks, both mature mRNA_{om} and high MW ovomucoid RNA species have accumulated. Analysis of 20 µg of nuclear RNA revealed the accumulation of the most abundant high MW species, band *g* (Fig. 4, left), whereas analysis of 100 µg of RNA revealed the accumulation of the three most predominant species larger than mRNA_{om}, bands *b*, *e* and *g*, (Fig. 3, right). Species *a*, *c*, *d* and *f* were not detected, probably because these are the least abundant of the high MW ovomucoid RNA molecules.

After short periods (1–2 h) of secondary oestrogen stimulation, the relative intensity of the ovomucoid RNA bands (Fig. 4, right) was similar to that observed after chronic oestrogen stimulation (Fig. 1, lane A; Fig. 2, lane C). The bands cor-

responding to species *g* and mRNA_{om} were of roughly equal intensity, whereas that of species *e* was of lesser intensity and that of species *b* even less. After longer periods (>4 h) of secondary stimulation, this pattern shifted. The concentration of mRNA_{om} increased at each time point so that 16 h after the DES injection a very intense mRNA_{om} band was observed. By contrast, the concentration of the most abundant high MW ovomucoid RNA species, band *g*, increased only slightly during this period. In addition, no significant increases in the concentration of ovomucoid species *e* were observed. Thus, 4–16 h after DES injection, mature mRNA_{om} was clearly more abundant than any of the high MW ovomucoid RNA species.

Fig. 1 Identification of ovomucoid mRNA sequences in high MW nuclear RNA. Nuclear or cytoplasmic RNA was isolated from the indicated tissues from White Leghorn chicks stimulated chronically with diethylstilboestrol (DES) as described previously⁷. Ovomucoid mRNA (~40% pure) was prepared from hen oviduct as previously described¹⁵. RNA was then subjected to agarose gel electrophoresis in the presence of 10 mM methylmercury hydroxide (Alfa) as described previously⁷. All procedures involving methylmercury hydroxide were carried out in a fume hood and all waste was disposed of as for hazardous chemicals. The RNA was transferred by blotting from the gel to diazobenzylxymethyl (DBM) paper by the method of Alwine *et al.*¹⁶. Following transfer the DBM paper (12×14 cm) was hybridised to the ³²P-labelled ovomucoid probe (3×10⁷ c.p.m., specific activity 5×10⁸ c.p.m. per µg) in the conditions used previously⁷. Following hybridisation, the DBM paper was washed 3 times in 200 ml of 0.5×SSC (75 mM NaCl, 7.5 mM Na citrate, pH 7.0) for 2 h at 65°C. This washing procedure significantly reduced the background during autoradiography. The DBM paper was then dried and autoradiographed for 16 h using a Dupont Cronex intensifying screen at -20°C. The probe specific for ovomucoid RNA sequences was prepared from a *Hha*I fragment of pOM100, a chimaeric plasmid which was previously constructed by our laboratory and contains an ovomucoid cDNA insert¹⁵. This fragment, which contained ~700 base pairs that correspond to the sequence of ovomucoid mRNA, was labelled by nick translation by a modification of the procedure used previously⁷. The reaction was carried out in a final volume of 10 µl which contained: 50 mM Tris, pH 7.8; 5 mM MgCl₂; 10 mM 2-mercaptoethanol; 0.5 µg of bovine serum albumin; 60 µM dATP, dGTP; 6 µM unlabelled dCTP, dTTP; 3 µM ³²P-dCTP, dTTP (2,000 Ci mmol⁻¹ each, Amersham) and 0.1 µg of DNA. These components were assembled on ice and then 28 pg of DNase (Worthington, DPFF) was added. The mixture was incubated at room temperature for 1 min and immediately cooled in an ice water bath. *E. coli* DNA polymerase (2 µl, 9 units, Boehringer Mannheim) was added and the mixture incubated at 14°C for 4 h. The reaction was stopped by the addition of 25 µl of 40 mM EDTA, 25 µl of *E. coli* DNA (4 mg ml⁻¹) and 3 µl of 20% SDS. Unincorporated dNTPs were separated from the labelled DNA by gel filtration on Sephadex G-50 in 10 mM Tris-HCl, pH 7.5, 100 mM NaCl. Radioactive fractions eluting in the void volume were pooled, made 0.2 M in Na acetate, pH 4.5, and precipitated by addition of two volumes of ethanol. The specific activity of the ³²P-DNA was 5–10×10⁸ c.p.m. per µg. A, Oviduct nuclear RNA, 20 µg. (High MW ovomucoid RNA species *c* and *f* were not detected in this preparation.) B, Ovomucoid mRNA purified to approximately 40%, 15 ng. C, Oviduct cytoplasmic RNA, 20 µg. D, Spleen nuclear RNA, 20 µg. E, Liver nuclear RNA, 20 µg. F, RNA isolated after mixing liver nuclei with oviduct cytoplasm, 20 µg. The position of 28S, 23S, 18S and 16S ribosomal RNA markers is indicated.

Fig. 2 Comparison of ovomucoid and ovalbumin nuclear RNA. Oviduct nuclear RNA from chronically DES-stimulated chicks, 20 μ g, was electrophoresed and transferred to DBM paper (2×14 cm), hybridised to the ^{32} P-ovalbumin probe (5×10^6 c.p.m., specific activity 5×10^8 c.p.m. per μ g) and autoradiographed (lane A). The probe specific for ovalbumin sequences was prepared from a *Hha*I fragment of a nearly full-length ovalbumin cDNA clone, pOV230, as described previously⁷. Following autoradiography, the ^{32} P-ovalbumin probe that was hybridised to the RNA bound to the DBM paper was eluted by incubation in 200 ml of 99% formamide, $0.1 \times$ SSC (15 mM NaCl, 1.5 mM Na citrate, pH 7.0) for 45 min at 65 °C. The completeness of the elution was checked by autoradiography (lane B). The DBM paper was then hybridised to the ^{32} P-ovomucoid probe (5×10^6 c.p.m., specific activity 5×10^8 c.p.m. per μ g) and autoradiographed (lane C).

Comments

We have demonstrated the existence in chick oviduct of multiple species of ovomucoid RNA larger than mature mRNA_{om}. These high MW forms of ovomucoid RNA are found in oviduct nuclei, but not in spleen or liver nuclei, nor in oviduct cytoplasm. They do not result from aggregation of mRNA_{om}. The high MW forms contain sequences complementary to the intervening sequences as well as to the structural sequences of the ovomucoid gene. Their accumulation in oviduct nuclei is regulated by oestrogen. These results suggest that ovomucoid mRNA may be synthesised by the processing of a large primary gene transcript and that the multiple bands of ovomucoid RNA larger than mRNA_{om} may represent transcripts at different stages of processing.

To date, mRNA precursors have been carefully characterised only for β -globin mRNA. A 15S globin RNA molecule has been demonstrated to be a precursor to mRNA by pulse-label and chase experiments²⁰⁻²⁴. Electron microscopic analysis of globin RNA-DNA hybrids has shown that this 15S molecule consists of a continuous transcript of the three structural and two intervening sequence regions of the β -globin gene^{25,26}. In addition, a smaller precursor has been identified that probably contains only one of the intervening sequences of the globin gene^{22,23}. These results suggest that discrete species of RNA may exist for each combination of intervening sequences. Thus, the observation that the species of ovomucoid RNA larger than mRNA_{om} are comprised of both structural and intervening sequences of the ovomucoid gene strongly suggests that the high MW species represent mRNA_{om} precursors that lose intervening sequences as they are processed.

The kinetics of accumulation in oviduct nuclei of ovomucoid RNA sequences after secondary oestrogen stimulation is also consistent with the hypothesis that the high MW forms are precursors of mRNA_{om}. First, the prominent high MW species of ovomucoid RNA were detected after only 1 h of secondary stimulation. Second, at early times (1-2 h) after oestrogen administration, the concentration of species g seems to be the same as that of mRNA_{om}. After longer periods (up to 16 h), the concentration of species g increased only slightly, whereas that of mRNA_{om} increased to much higher levels. Although other explanations are possible, this differential accumulation is consistent with the hypothesis that the high MW species of ovomucoid RNA are efficiently processed to form mature mRNA_{om}. If they are precursors, this species should be detected before mRNA_{om}. Although this was not observed, it is possible that accumulation of high MW forms of ovomucoid RNA before that of mRNA_{om} might be observed if oviduct nuclear RNA is analysed within <1 h of DES injection. However, these detailed kinetic studies are difficult to control with intact animals and are perhaps better approached using an organ culture system where newly synthesised RNA may be radioactively labelled.

As the largest species of ovomucoid RNA is fivefold larger than mRNA_{om}, at least 80% of the ovomucoid gene may be intervening sequence DNA. In comparison, we estimate the ovalbumin gene to contain about four times more DNA than required to encode mRNA_{ov}. Thus, the overall organisation and structure of the ovomucoid gene is similar in complexity to that previously described for the ovalbumin gene^{11,12}. However, studies of the ovomucoid RNAs may offer advantages over those of the ovalbumin RNAs in the elucidation of precursor-product relationships. First, the fraction of nuclear ovomucoid RNA that is in the form of high MW species seems to be greater than that of nuclear ovalbumin RNA. Second, the ovomucoid

Fig. 3 Identification of ovomucoid intervening sequences in high MW ovomucoid nuclear RNA. For these experiments a hybridisation probe was initially prepared from a clone, selected from a library of chicken DNA fragments that were cloned in Charon 4A phage containing a 15-kilobase ovomucoid natural gene insert. This clone, which will be described in detail elsewhere²⁷, seems to contain all the structural and intervening sequences of the ovomucoid gene. Total DNA was isolated from the cloned phage, labelled with ^{32} P by nick translation and used as a hybridisation probe. Subsequent experiments in which the cloned ovomucoid fragment described in the accompanying paper¹⁹ was used as a hybridisation probe gave identical results. Oviduct nuclear RNA from chronically stimulated chicks, 20 μ g, was electrophoresed, transferred to DBM paper (2×14 cm) and allowed to hybridise to the ^{32} P-labelled natural ovomucoid gene probe (10^7 c.p.m., specific activity 6×10^8 c.p.m. per μ g) in the absence (lane A) or presence (lane B) of unlabelled ovomucoid mRNA as a competitor. The conditions for competition were as follows: ovomucoid mRNA (20 μ g, ~20% pure) was preincubated with the ^{32} P-labelled probe in 1.0 ml of hybridisation buffer at 42 °C for 1 h. The mixture was diluted to 5.0 ml with hybridisation buffer and then hybridised to the DBM paper containing the bound nuclear RNA. Autoradiography of both samples was for the same length of time (about 1 week).

Fig. 4 Induction of high MW ovomucoid RNA by secondary oestrogen stimulation. Oviduct nuclear RNA was isolated from chicks that had received daily subcutaneous injections of 2.5 mg of DES for 14 d and subsequently withdrawn from hormone for 14 d (W). In addition, hormone-withdrawn chicks were injected with a single dose of 2.5 mg of DES and the oviduct nuclear RNA was isolated after 1, 2, 4, 8 and 16 h. The RNA was electrophoresed, transferred to DBM paper (15 × 15 cm) and hybridised to the ^{32}P -ovomucoid probe (3.3×10^7 c.p.m., specific activity 8×10^8 c.p.m. per μg). Left panel, 20 μg of nuclear RNA was analysed; right panel, 100 μg of nuclear RNA was analysed.

RNA bands are well separated from each other on the gel, whereas the ovalbumin RNA bands are more closely spaced. These two features should enhance the assessment of planned kinetic labelling studies as well as the purification of individual species of high MW nuclear RNA.

R_{ot} analysis has previously shown that the concentration of total ovomucoid RNA sequences in oviduct nuclei gradually increased from approximately 1 part per 10^6 to 30 parts per 10^6 after 16 h of secondary oestrogen stimulation⁹. These results are consistent with the accumulation of individual nuclear ovomucoid RNA species shown in Fig. 3. Both analyses clearly show that the low concentration of mRNA_{om} in withdrawn oviduct polysomes⁸ is not the result of nuclear sequestration of immature or mature forms of mRNA_{om} . In addition, by hybridising nuclear radiolabelled mRNA_{om} to an excess of cloned

ovomucoid DNA, we have been able to estimate the rate of mRNA_{om} synthesis and have shown it to depend on oestrogen⁹. Taken together, these results are consistent with regulation of the ovomucoid gene by oestrogen mainly through control of its transcription.

The library of chicken DNA fragments which were cloned in Charon 4A phage was provided by Tom Maniatis and Richard Axel. We thank Ms Melanie Vinion and Mr William Tate for technical assistance. This work was supported by NIH grant HD-8188, the Baylor Center for Population Research and Reproductive Biology. J.L.N. is the recipient of USPHS Postdoctoral Fellowship GM 06893-01. All cloned DNA was prepared using a P3 facility in accordance with the NIH guidelines.

A model for the unpulsed light from the Crab pulsar

THE recent detection¹ of a significant unpulsed fraction of the light from the Crab Nebula pulsar invites comment regarding models for the beaming of the radiation. One such model is the relativistic beaming model²⁻⁴ in which the radiation comes from a region near the speed-of-light cylinder of a neutron star magnetosphere. Here the predictions of this model are investigated, using model parameters found by Ferguson *et al.*⁵ from fits to the polarisation characteristics of the Crab pulsar, and which were subsequently found⁶ to agree with the change of light curve with colour of the secondary pulse.

The parameters are β , the fraction of the light cylinder radius at which the radiation is emitted; T , the angle between the rotation equator and the line of sight; and ϵ , the spectral index. It is assumed that in the frame of reference of the emission regions co-rotating with the neutron star the radiation is unbeamed, and

only becomes pulsed to an outside observer because of the Doppler effect and the aberration of light.

In the following, quantities in the corotating frame are primed, and those to an outside observer unprimed. Subscript 1 refers to the main pulse emission and 2 to the secondary pulse emission. Subscripts max and min refer to the maximum and minimum of the quantities observed by an outsider. In the relativistic beaming theory, the intensity

$$I = RI$$

where $R = (1 - \beta \cos \theta \cos T)^{-3-\epsilon}$, θ is the angle in the emission region orbit between the emission region and the point of minimum radial velocity, and ϵ is the spectral index from $I \propto \nu^{-\epsilon}$. $\beta_1 = 0.65$, $\beta_2 = 0.50$, $T = 25^\circ$ (from ref. 5), and $\epsilon = 0.2$ (from ref. 7) Then,

$$I_{1,\text{peak}} \approx I_{1,\text{max}} + I_2(\theta_2) \quad (\theta_1 = 0)$$

$$I_{2,\text{peak}} \approx I_{2,\text{max}} + I_1(\theta) \quad (\theta_2 = 0)$$

and $I_{\min} \approx I_2(\theta_{2m}) + I_1(\theta_{1m})$

Here, $I_{\min}$ is the minimum of the observed intensity, taken to occur midway between the secondary and main pulses, θ_{1m} is the value for emission region 1 at that time, and θ_{2m} is the corresponding value for emission region 2. θ_1 is the value of θ for emission region 1 at the time of the secondary pulse peak and θ_2 is the value for emission region 2 at the time of the main pulse peak.

To compute the values of θ , we must relate the observed pulse longitudes to phases in the emission region orbits through the relationship⁸

$$\theta_{\text{obs}} = (\theta - \beta \sin \theta \cos T)$$

Taking the separation of the main and secondary pulses to be 146° , we have

$$146^\circ = -(\theta_2 - \beta_2 \sin \theta_2 \cos T) = (\theta_1 - \beta_1 \sin \theta_1 \cos T)$$

and at the midpoint of their greatest separation,

$$\begin{aligned} \frac{(360 - 146^\circ)}{2} &= (\theta_{2m} - \beta_2 \sin \theta_{2m} \cos T) \\ &= -(\theta_{1m} - \beta_1 \sin \theta_{1m} \cos T) \end{aligned}$$

Solving for the various values of θ and substituting, we find

$$I_{1,\text{peak}} \approx 17.22I'_1 + 0.329I'_2,$$

$$I_{2,\text{peak}} \approx 6.90I'_2 + 0.247I'_1$$

and

$$I_{\min} \approx 0.345I'_1 + 0.458I'_2$$

Now from the tabulated light curves with $I_{\min}$ subtracted⁶ we find

$$(I_{2,\text{peak}} - I_{\min}) = 0.270(I_{1,\text{peak}} - I_{\min})$$

Solving this for I'_2 , we find $I'_2 = 0.719I'_1$, which shows that the intensities of both pulses are roughly equal in their emission frames. Finally, on substituting we have $I_{\min}/I_{1,\text{peak}} \approx 0.039$, or the minimum in observed intensity should be $\sim 3.9\%$ of the main pulse peak.

The observed values of Peterson *et al.*¹ are $3.6\% \pm 0.7$ and $3.7\% \pm 0.8$, using two independent techniques. The agreement between the theoretical and observed values is remarkable. The simplistic model predicts an underlying component of emission almost identical to that observed, and does this with no free parameters. Of course, to explain the Crab pulsar's asymmetrical pulse shapes, Cocke and Ferguson⁶ postulated a certain amount of intrinsic beaming to supplement the relativistic beaming. Also, the recent resolution of the Crab pulsar optical main peak⁹ indicates a width consistent with $\beta \approx 0.9$. If this pulse width is indicative of the true value of β for the main peak, the unpulsed light would need to come mainly from the secondary pulse emission region, which has a much lower value of β . It is not clear whether the inclusion of these effects would worsen the numerical agreement arrived at by the above analysis. However, the fact that this simple version of the model agrees even roughly with the observations, using the same model parameters necessary to fit the polarisation and change of light curve with colour, is further evidence of the power of the relativistic beaming model for the Crab Nebula pulsar.

With the new information about the unpulsed emission, it would be worthwhile to reanalyse the old Crab polarisation data in the hope of correcting the percentages and angles near the polarisation minima, which are most affected by errors in the subtracted noise level, and to see how the polarisation behaves in the regions between pulses. If the model given here is correct, the between-pulse polarisation should be high and smoothly vary from one emission region to the next.

Ion-induced dipole H_n^- clusters

THERE has long been an interest in the study of ion-induced dipole clusters of the type H_n^+ (n , odd integer). These positive clusters may be present in gaseous nebulae^{1,2}, and Clappitt and Gowland³ have discovered in mass spectrometer experiments such H_n^+ ions for $3 \leq n(\text{odd}) \leq 99$. The ions are very weakly bound because of the nature of the ion-induced dipole forces involved, and thus must be produced at low temperatures. In these experiments a layer of hydrogen gas is deposited on a metal surface maintained at 3 K in a baked vacuum apparatus operating at $\sim 10^{-10}$ torr. The surface is swept by a 23 eV electron beam and the ions thus created are focused into a quadrupole filter and detected. The surface mechanism for production of the ions is not understood but the presence of grains in the interstellar medium might provide surfaces which could play an analogous role in similar conditions of low pressure and temperature. To study the binding energy and geometry of such clusters we performed *ab initio* Hartree-Fock-Roothaan calculations⁴, using a contracted s-type Gaussian orbital basis. Our previous use of this type of calculation⁴⁻⁷ for ion molecule complexes which dissociate into closed shell fragments, indicated that reliable results can be obtained. The results shown in Fig. 1 and Table 1 are all based on this type of calculation implemented with the Gaussian 70 program^{8,9} using four gaussians per hydrogenic s-orbital. As expected, we found the positive cluster to be quite weakly bound, that is the binding energy was of the order of 1 kcal mol^{-1} against dissociation according to

(the largest and smallest binding energies found were $6.0 \text{ kcal mol}^{-1}$ for H_3^+ and $0.3 \text{ kcal mol}^{-1}$ for H_{15}^+). In our calculations the geometries of the positive clusters were dominated by the strongly bound triangular nucleating centre H_3^+ . Each member of the series H_n^+ , $5 \leq n(\text{odd}) \leq 15$ is formed by the addition of one hydrogen molecule to the basic structure of the previous member in the series. We report here calculated binding energies and geometries for the negative ion induced dipole clusters H_n^- , $5 \leq n(\text{odd}) \leq 13$.

These ions have not apparently been previously investigated theoretically or experimentally although a search for such clusters was suggested by Clappitt and Gowland³. It would be interesting to investigate whether the binding energies are of the same order of magnitude as in the analogue clusters H_n^+ , as it has been established that in this case the clusters may be experimentally produced in favourable conditions². As in the case of

Table 1 Calculated binding energies and geometrical parameters for hydrogen clusters H_n^-

Molecule	Binding energy (kcal mol)	Geometric parameters		
		$a(\text{\AA})$	$b(\text{\AA})$	$c(\text{\AA})$
H_3^-	8.91	2.05	0.74	
H_5^-	7.30	2.10	0.74	
H_7^-	6.52	2.12	0.74	
H_9^-	5.59	2.15	0.74	
H_{11}^-	4.00	2.21	0.74	2.27
H_{13}^-	3.97	2.34	0.74

the positive clusters⁴, the conditions in gaseous nebulae may be suitable for weakly bound negative clusters to exist (some of the conditions that have been laid down¹⁰ for a possible molecular source of the diffuse interstellar absorption lines are in fact met by the H_n^- and H_n^+). We expected that the geometries for the negative ions would be quite different than for the positive ions as both the charge sign and the geometry of the nucleating centre differ. In the latter, the tightly bound triangular geometry of the nucleating centre H_3^+ governs the geometries of the clusters of increasing mass. It is energetically favourable for a positive charge to be approached by a hydrogen molecule along a line perpendicular to its bond. In the former, the nucleating centre is a H^- ion which presents an essentially spherical static electric field to H_2 molecules in the clusters. It is energetically favourable for a negative charge to be approached by a hydrogen molecule along a line through its bond. The molecular ion H_3^- dissociates in ordinary conditions according to the reaction

although it^{11,12} exhibits a shallow potential minimum (about 0.8 kcal mol⁻¹ for a linear geometry with H^- about 2.41 Å to the nearest atom in H_2) capable of supporting discrete vibrational and rotational states in favourable experimental conditions. Our calculations also reproduce the shallow potential minimum for H_3^- in a linear geometry, found by previous workers. At the geometry of minimum energy we find the nucleating centre H^- at a distance of 2.05 Å from the nearest atom in the H_2 fragment. The H_2 fragment has a bond distance equal to 0.74 Å, the same as for the free H_2 molecule.

Our new results are summarised in Fig. 1 and Table 1. All these results correspond to calculations in which the total energy of the system has been optimised with respect to all geometrical parameters (bond lengths and bond angles) within the system.

For each molecule the energy surface displayed a potential well whose minimum was sufficiently deep enough to support a few discrete vibrational and rotational states and which geometrically correspond to ion-induced dipole bonds. All the clusters contain polarised H_2 fragments (having a bond distance corresponding to the free H_2 molecule) attached to the negative ion nucleating centre H^- . In fact the geometries adopted by the various clusters under energy optimisation correspond to Gillespie's rules^{13,14} of molecular geometry based on minimisation of repulsion of electron pairs.

Table 1 shows that all of the clusters displayed are bound by a few kilocalories per mole against the dissociation

a result which is analogous to the previous calculation for the experimentally known H_n^+ molecular ions.

The binding energy of the H_5^- ion is 7.3 kcal mol⁻¹, and has a linear geometry ($C_{\infty v}$) with the nucleating centre 2.10 Å from either H_2 fragment. H_7^- has a binding energy of 6.52 kcal mol⁻¹. The geometry of the ion is planar and trigonal (D_{3h}) with an H_2 fragment to nucleating centre distance of 2.12 Å. H_9^- is bound by 5.59 kcal mol⁻¹ with a tetrahedral geometry (T_d) and fragment to centre distance 2.15 Å. The ion H_{11}^- decreases in bonding energy to 4.00 kcal mol⁻¹ and has a geometry which is trigonal bipyramidal (D_{3h}) with fragment to centre distances 2.21 Å and 2.27 Å as shown in Fig. 1. Finally H_{13}^- is found in its minimum energy configuration to be bound by 3.97 kcal mol⁻¹ in an octahedral geometry (O_h) with fragment to centre distance 2.34 Å. This last result answers the question raised by Clappitt and Gowland³ on whether H_{13}^- might be the most stable of the negative clusters. We find that it is not. In fact Table 1 shows that for the negative ion clusters studied there is a continual decrease of binding energy as the size of the cluster grows.

In conclusion our results indicate that the negative ion clusters H_n^- (n is odd) are bound by a few kilocalories per mole, the same order of magnitude as found earlier for binding energy of the positive ion clusters H_n^+ (n is odd) which are experimentally known. The negative ions may form in favourable conditions.

We thank Barbara Rubenson for constructing Fig. 1.

Polonium haloes in mica

GENTRY¹ has reported that some anomalous haloes found in ancient mica seem to arise from the α -decay of polonium isotopes only, without any observable long-lived β -emitting precursors. Fremlin² suggested that these might occur as a result of the diffusion of β -emitting radiogenic lead isotopes from relatively distant or widely dispersed uranium or thorium inclusions, and the absorption of the lead ions by small pre-existing inclusions of foreign material. As Gentry³ pointed out,

Fig. 1 Apparatus used to introduce lead into mica at elevated temperatures and under an applied electrical field. The muscovite mica sheet ($\sim 3 \times 2.4 \text{ cm}^2$, $200 \mu\text{m}$ thick) is held tightly, with the help of screws, between two stainless-steel cylinders (diameter 8 mm, height 2 cm). Central holes (diameter 3 mm, depth 6 mm) in these cylinders are filled with lead. The electrical field ($\sim 10^5 \text{ V cm}^{-1}$) is applied across the sample through insulated wires, and the whole assembly is placed inside a furnace. 1, Screw; 2, cylinder; 3, mica; 4, lead; 5, insulator.

this would involve abnormally high diffusion rates for lead. We have carried out experiments that demonstrate the possibility of such high rates. Here we also discuss the reasons for the absence of an excess of observable tracks left in mica by the recoil of the lead daughter when α -decay takes place in the polonium isotopes.

The method used in this work involved two major techniques: (1) introducing lead into mica and establishing conditions for diffusion; and (2) radioactivating to transform some of the lead nuclei to radioactive products, and the detection of the radioactivities by autoradiography using plastic nuclear track detectors. These two stages are considered below.

To study the diffusion of lead in mica, we first need to introduce an adequate number of lead atoms into the samples. This has been done by using the apparatus shown in Fig. 1. This

apparatus comprises two identical steel cylinders of diameter 8 mm and height 2 cm. Each cylinder has a coaxial hole of diameter 3 mm and depth 6 mm. These holes were filled with lead, and the mica sample ($\sim 3 \times 2.4 \text{ cm}^2$ in area) was clamped between the cylinders by the screws shown. The cylinders were connected to a power supply by heat-resistant insulated wires. The apparatus was then placed in a furnace at the desired temperature for periods of up to 48 h.

An electrical field ($\sim 10^5 \text{ V cm}^{-1}$) was applied at right angles to the cleavage planes of the mica. Any field-induced diffusion of lead was parallel to the field and between the areas in contact with lead (within a circle of diameter 3 mm), or at most between the areas over which the potential difference was applied (within a circle of diameter 8 mm). Any diffusion outside this region would be independent of the applied electric field.

A variety of activation methods have previously been used for lead analysis. For determination of the spatial distribution of lead in mica the reactions producing γ and/or β emitters are not suitable, as the interference from other γ and/or β emitters produced in the matrix is always very high.

We used ^3He and ^4He bombardments to produce α -particle-emitting isotopes of polonium according to reactions of the type $\text{Pb}(\text{He}, n)\text{Po}$. α -particles from the polonium could then be detected using cellulose nitrate films (Kodak LR-115, type II; Kodak-Pathé).

Rectangular pieces of muscovite mica ($\sim 3 \times 2.4 \text{ cm}^2$) of thickness $\sim 200 \mu\text{m}$ were placed between the two cylinders of the apparatus shown in Fig. 1. The assembly was placed in a furnace at a desired temperature and an electrical field of $\sim 10^5 \text{ V cm}^{-1}$ was applied between the cylinders. After several hours of diffusion (across and along the cleavage planes of mica sample), the sample was removed from the apparatus and a few layers of mica were peeled away from each face of the sample to remove any surface contamination. The remaining part of the sample was irradiated with ^3He or ^4He ions, of energy 30 MeV or 40 MeV respectively, and with a current of $2 \mu\text{A}$ for a period of 2 h on each face. To avoid the possibility of the disturbance of the lead distribution on the surfaces of mica during the irradiation, a very thin layer of mica was again peeled off from each face of the sample. Cellulose nitrate films (LR-115 type II) of the same size as the sample were then placed in close contact with

Fig. 2 Number of tracks per unit area measured along axis AB (see insets). For *a*, *b*, *c*, the lead is in contact with the top surface of mica in the circle between points 1 and 2. The potential difference was applied at right angles to the mica surface over a circular region between points 3 and 4. *a*, Diffusion temperature 500°C ; diffusion time, 36 h; unit area examined, $2 \times (2 \times 9) \text{ mm}^2$. *b*, Diffusion temperature, 400°C ; diffusion time, 24 h; unit area examined, $2 \times 2 \text{ mm}^2$. *c*, Diffusion temperature, 250°C ; diffusion time, 48 h; unit area examined, $2 \times (3 \times 2) \text{ mm}^2$.

each surface of the sample. After several days of exposure, the plastics were etched in a 25% solution of sodium hydroxide at a temperature of 55 °C for 2 h. The resulting α -tracks were counted under an optical microscope, using an overall magnification of $\times 40$.

This diffusion experiment was carried out at temperatures of 600, 500, 400 and 250 °C for different lengths of time. Figure 2a, b, c shows some of the results.

Although none of the results shown in Fig. 2a, b, c can provide an accurate numerical value for the migration velocity of lead atoms in mica, they show that diffusion of lead in mica is a fairly rapid process and that the traversal of at least 1 cm was possible in 24 h over a considerable range of temperatures.

It may be true, as assumed by Gentry³, that the diffusion coefficient of lead is only of the order of $10^{-18} \text{ cm}^2 \text{ s}^{-1}$ at 20 °C in the case of field-free diffusion across the cleavage plane. Our observations suggest that, even at 500 °C and with an applied field of 10^5 V cm^{-1} , the diffusion coefficient D across the planes is $< 6 \times 10^{-10} \text{ cm}^2 \text{ s}^{-1}$. But Fig. 2a, b, c indicates that, at elevated temperatures, it must be much higher along the cleavage planes than the above-mentioned value: for example, $D > 3 \times 10^{-6} \text{ cm}^2 \text{ s}^{-1}$ at 250 °C in the field-free area.

Gentry³ has pointed out that if active lead or polonium isotopes do diffuse through mica, recoil tracks should be observable from nuclei, which had undergone α decay during their diffusion through the mica. Such tracks should have appeared as 'excess' α -recoil tracks because during diffusion, each of the daughters recoiling from its α decay would have produced a separate track, whereas in the case of stationary U, Th nuclei the daughters of which did not diffuse away, the whole decay chain would have looked like a single, local recoil. No such excess recoil tracks have, in fact, been observed. We explain this apparent anomaly as follows.

Recoil tracks produced by α -decaying nuclei (α -RT) have an etchable range in mica of $\sim 0.01 \mu\text{m}$ (a combined fission-fragment etchable range of $\sim 20 \mu\text{m}$). The much shorter α -recoil tracks would fade more easily than the longer, more energetic, fission tracks, when subjected to thermal annealing in nature (see refs 4, 5; this conclusion is also supported by our unpublished data). The work of Nagpaul *et al.*⁶ confirms this fact.

They have shown that, in a biotite sample (from the Nellore mica belt of India), the length reduction of fossil fission tracks due to natural annealing at normal temperatures ($\sim 20^\circ\text{C}$) was $\sim 12\%$, which corresponds to 6.5% reduction in the apparent fossil-fission track density. This phase had been preceded by a high-temperature period lasting for about 190 Myr, during which the average temperature of the region must have been about 150 °C. This earlier period of geological annealing at 150 °C resulted in a reduction of 71% in fission track length or 65% reduction in apparent fission track density.

As α -recoil tracks fade more easily than fission tracks, the reduction in the density of the former during both geological phases must have been high. Such severe losses in the density of α -RT could easily reduce the recoil/fission track ratio sufficiently to create the impression that the expected 'excess' recoil tracks during the diffusion of lead or polonium isotopes had never occurred.

Our experimental results show that the diffusion of lead in mica along the cleavage planes is a rapid process. Hence, if our explanation of the lack of observable excess α -recoil tracks is accepted, the diffusion of lead isotopes from decay chains could well cause some of the polonium haloes. In that case ^{210}Pb is available (β^- , $T_{1/2}$ 22 yr), in one uranium series (^{238}U); and ^{211}Pb (β^- , $T_{1/2} = 38 \text{ min}$) in the other (^{235}U). Furthermore, the ^{232}Th series, which eventually produces ^{208}Pb , has ^{212}Pb with a half life of 19.6 h as a carrier.

We do not rule out the possibility that the diffusion of polonium itself may be a contributory—or even in some cases the main—cause. Experiments on this are in progress. Note that the three most commonly used minerals for halo investigations, biotite, fluorite and cordierite, all have cleavage properties; although, in the case of the cordierite, cleavage is not perfect. In

such materials, fast ion-conduction parallel to the cleavage planes could be expected and would probably be associated with high mobilities at elevated temperatures.

We thank Drs P. F. Green and D. K. Ross for discussions.

Secondary batteries powered by forced ionisation

SECONDARY batteries normally store energy by accumulation of electrode products formed by electron transfer, that is, production of a reducing agent at one electrode and an oxidising agent at the other electrode. I have demonstrated a storage battery concept that depends on the energy associated with ionisation of slightly dissociated compounds, for example, forcing the equilibrium $\text{H}_2\text{O} \rightleftharpoons \text{H}^+ + \text{OH}^-$ to the right stores energy. A cell for recovery of this energy as electricity is described here. De Kőrös and Zeigerson have mentioned the possibility of a primary battery based on these principles¹.

The key element of such a cell must allow union of the ions at a fixed phase boundary. Removal of H^+ from one solution and OH^- from the other produces a potential which is related to the equilibrium constant for the reaction. The phases may be separated by a bipolar ion exchange membrane or a bipolar depolarising electrode. The cell configuration for each type of separator is shown in Figs 1 and 2. The flow of ions indicated is for the charging cycle and flow is reversed for discharge. The net process is: $\text{H}_2\text{O} + \text{MX} \rightleftharpoons \text{MOH} + \text{HX}$.

Fig. 1 Schematic for repeating cell in a forced ionisation secondary battery using a bipolar ion exchange membrane.

Bipolar ion exchange membranes have been made by lightly fusing a cation exchange membrane to an anion exchange membrane². The alternative procedure of de Kőrös and Zeigerson¹ forms both the anion and cation exchange sites on opposite sides of a sheet of sulphochlorinated polyethylene. The use of bipolar ion exchange membranes for production of acid and base has recently been discussed in considerable detail^{3,4}. During this cycle, that is charging, inefficiency is associated with migration of either hydrogen or hydroxyl ions across the ion exchange barrier.

Fig. 2 Schematic for repeating cell in a forced ionisation secondary battery using a bipolar depolarising electrode. A, anion exchange membrane; C, cation exchange membrane.

A depolarising bipolar electrode has been used in this laboratory for production of an acid in a base. The same type of cell has now been used to produce electricity by neutralisation of acid and base. The cell is shown in Fig. 3. Hydrogen electrodes are used to convert the potential produced by migration of cations across the cation exchange membrane. The migration of hydroxyl ions to the acidic solution is a source of inefficiency as the potential is immediately nullified by the free migration of a sodium ion in the same direction.

The production of electrical energy from acid and base was carried out as follows. The entire system was placed under a positive pressure of hydrogen and the solution compartments filled with aqueous sodium phosphate. The central palladium foil was made cathodic and the end foils anodic⁵. This caused a net transport of hydrogen into the central palladium foil to speed equilibration with the external hydrogen. After equilibration acidic and basic solutions were passed in. The current-voltage relationships obtained are shown in Fig. 4.

These experiments demonstrate the use of two working fluids (water and methanol). As shown by methanol, compounds with lower ionic dissociation give higher cell voltage. The theoretical cell voltage associated with a number of equilibrium systems is calculated in Table 1.

Fig. 3 Schematic for cell with net reaction $\text{H}^+ + \text{OH}^- \rightarrow \text{H}_2\text{O}$. Electrode reactions, left to right:

Pd, activated palladium foil; C, Na ion cation exchange membrane.

The higher voltage systems place limits on the counter ions associated with the above ions of the charged state. These ions must move readily through ion exchange membranes and form ionic compounds with highly active ions. The alkali metal ions and the counter ions of superacids would be required in the most energetic systems. In addition, the salt formed by these ions must be sufficiently soluble to give good electrical conductivity. It is apparent that this scheme requires a bipolar member stable to extremely strong acids and bases. In these circumstances, the bipolar depolarising electrode may be more suitable than the bipolar ion exchange membrane. The latter are generally subject to degradation on the anion exchange side at extremely basic conditions.

The cells shown in Fig. 1 also require an anion exchange and a cation exchange membrane for each repeating unit. The anion exchanger operates between a salt solution and a strongly acidic solution. As a result, high efficiency for hydrogen ion rejection is necessary. However, chemical resistance will be less demanding than that in the corresponding part of the bipolar ion exchange membrane. Similar considerations apply to the cation exchange portions.

Table 1 Theoretical repeating cell e.m.f. for several working fluids as a function of the equilibrium shown

	$-\log$ Equilibrium constant	cell e.m.f.
$\text{HF} = \text{H}_2\text{F}^+ + \text{F}^-$	3	0.18
$\text{H}_2\text{O} = \text{H}_3\text{O}^+ + \text{OH}^-$	14	0.83
$\text{NH}_3 = \text{NH}_4^+ + \text{NH}_2^-$	35 (6)	2.06
$\text{CH}_4 = \text{CH}_5^+ + \text{CH}_3^-$	~ 60	~ 3.5

The high mobility of hydrogen and hydroxyl ions make high rejections of these ions particularly difficult. The use of any other working fluid with less mobile ions would be desirable from this point of view. However, such ions will add to the internal resistance of the bipolar ion exchange membrane.

The systems discussed all involve transport of H^+ or H^0 , but this is not essential. Any of a large number of liquids which yield ions under high electric field might be suitable. For example, the equilibria

are reported.

Such working fluids could greatly reduce the demands on the anion exchange component of the bipolar membrane. At the same time, the character of the cation exchange portion becomes more critical.

The metal foil depolarising bipolar electrode is obviously not suitable for such working fluids. The basic requirements for this component of the system are the same as those for gas depolarised electrodes—electronically conductive, liquid impermeable, but gas permeable. The surface should also be catalytic for the desired reaction, for example, $\text{Cl}^- \rightarrow \text{Cl}^0 \rightarrow \text{Cl}^+$. Such electrodes are readily built but any practical system requires a balance of mechanical strength and rapid gas permeability which is difficult to achieve.

Fig. 4 Current-voltage plot for cells powered by the net reaction $\text{H}^+ + \text{OH}^- \rightarrow \text{H}_2\text{O}$. $\times$, 17% aqueous phosphoric acid, 20% aqueous sodium hydroxide; Δ , 20% aqueous sodium dihydrogen phosphate, 20% aqueous sodium hydroxide; $\circ$, Phosphorus pentoxide in methanol 25 gl^{-1} , sodium methoxide in methanol 25 gl^{-1} . Current density was established by a variable external resistance.

At the ends of any assembly of cells of this type, electrodes which convert ionic charge to electronic charge are required. The hydrogen electrode was used in the above experiment. Electrodes such as those used in secondary batteries may be suitable. For example, nickel electrodes may be suitable for an aqueous cell provided they are placed in strongly alkaline compartments. The electrodes would operate on the reversible $\text{Ni}^{2+} \rightleftharpoons \text{Ni}^{3+}$ cycle with no net contribution to energy storage.

Evidence for a higher natural uranium content in world rivers

α -SPECTROMETRIC uranium isotopes analyses on groundwater samples from the highly fertilised Handschuhsheimer Feld area in Heidelberg suggest that the uranium content of the groundwater is primarily of natural origin; uranium derived from phosphate fertilisers is adsorbed on the uppermost soil layers and the uranium content of the water is correlated to the HCO_3^- content. A similar relationship between uranium and HCO_3^- also applies for world rivers and lakes. We show here that this indicates that a low uranium content is due to low HCO_3^- contents and not to lower contamination levels. On the basis of this correlation the average natural uranium content of world rivers, for 35% of the water input to the ocean, was calculated to be $0.3 \mu\text{g l}^{-1}$.

The uranium content of river waters varies by about two orders of magnitude, from $0.04 \mu\text{g l}^{-1}$ for the Amazonas, to a few $\mu\text{g l}^{-1}$ (refs 1-5). This higher uranium content is, however, suspected to be partly of anthropogenic origin due to uranium derived from phosphate fertilisers⁵. In fact, compared with normal soil and rock material with a few p.p.m. uranium, phosphate fertilisers have up to 200 p.p.m. uranium. This fertil-

iser uranium is thought to contaminate the ground and eventually the river-water. Thus the question arises of whether the present-day estimates for the average uranium input by rivers to world oceans are representative of all geological time and therefore applicable to steady-state model calculations^{4,6}. However, several factors seem to contradict the assumption of a high uranium-pollution level of river water: a clear-cut relationship between the uranium and phosphate content of the water has not been found. Rivers show a significant ^{234}U excess, that is, the activity ratio $\text{AU} = ^{234}\text{U}/^{238}\text{U} > 1$ (ref. 7), whereas fertiliser uranium has an $\text{AU} \sim 1$, as in the case of soil and rock material. In addition, high uranium contents were also measured for some Indian rivers with catchment areas of low fertilisation⁸. Moreover, the uranium concentration in natural waters is assumed to be mainly controlled by the redox potential of the environment and by CO_2 (ref. 7).

To estimate the uranium contribution to groundwater by fertilisers and hence to evaluate the natural average uranium content of rivers, we have carried out uranium-isotope analyses on five groundwater samples from the highly fertilised area of the Handschuhsheimer Feld, Heidelberg, which has been used for horticulture for several decades (Table 1). Results are also presented here for three groundwater samples from an unfertilised forest area some 15 km out of Heidelberg, for the commercially available fertilisers, as commonly applied in this area (Table 2), and for a number of major German rivers, including the Neckar, that receives a groundwater contribution from the studied area (Table 1).

A 10-l sample was spiked with ^{232}U (in weak HCl solution), left at least 2 h for equilibration of uranium isotopes, then filtered (paper filter) and passed through a column containing 3 g of Hyphan-resin⁹ ($\text{pH} > 5$, flow-rate 40 ml min^{-1}). Back-extraction was achieved with 50 ml 2 M HCl. The pH of this solution was then adjusted to ~ 5 with NH_4OH , uranium extracted into 20 ml TTA (0.1 M in benzene) and back-extracted into 20 ml 1 M HCl. The TTA extraction and back-extraction steps were then repeated. Adding concentrated HCl, the final aqueous solution was made 8 M and passed through a Dowex I resin to separate uranium from thorium isotopes. The following electroplating step and measurement of the uranium isotopes have been described elsewhere¹⁰. Counting times around 3,000 min made the counting errors smaller than 5%, even if the uranium content was as low as $0.1 \mu\text{g l}^{-1}$.

In this area of the Rheinebene, groundwater recharge of about 200 mm yr^{-1} has been estimated from the downward

Fig. 1 Plot of the uranium content against HCO_3^- content for all world rivers and lakes, where both data are available. The circles indicate Texas rivers. The straight line is a linear fit for all values, the dotted lines show the 1σ deviation range. Apart from our values, U and HCO_3^- were not measured contemporarily (refs for the uranium contents are 1, 3–6 and 19–23, for the HCO_3^- values are 24, 26). The uncertainty in the HCO_3^- values exceeds 30% in some cases.

movement of precipitation water in the unsaturated zone, determined by tritium tracer experiments (sandy soil near Sandhausen-Heidelberg)¹¹. In addition a groundwater recharge of 190 mm yr^{-1} has been calculated from the bomb tritium vertical distribution in the shallow groundwater body of Sandhausen¹². In the Handschusheimer Feld, groundwater recharge by local rainfall is assumed to be about 113 mm yr^{-1} (data from Wasserwirtschaftsamt Heidelberg), as estimated using conventional hydrogeological methods. Both estimates agree with the bomb tritium standing crop in the shallow groundwater (see Table 1). At a fertilisation rate of $100 \text{ g m}^{-2} \text{ yr}^{-1}$, as commonly applied, some 12 g of nitrogen are annually incorporated to the soil. With an average groundwater

supply of 113 mm one can determine that some 25% of the fertiliser nitrate goes into the shallow groundwater, raising the natural nitrate concentration by some mg l^{-1} (as in the Südkreis Mannheim area) to values as high as 126 mg l^{-1} . (Water is used for irrigation only.) Although fertilisers have a high uranium content (Table 2) the uranium content of the shallow groundwater is even lower than that of the deeper groundwater, having lower nitrate and tritium contents. At the fertilisation rate of $100 \text{ g m}^{-2} \text{ yr}^{-1}$, taking into account an average uranium content of fertilisers of 50 p.p.m., the contamination should be as high as $40 \mu\text{g l}^{-1}$, if all uranium was transported in the newly formed groundwater.

The conclusion must be that more than 95% (2σ) of uranium supplied with the fertilisers are retained in the uppermost soil layers. This conclusion is corroborated by the fact that the activity ratio of the uranium isotopes $^{234}\text{U}/^{238}\text{U}$ of the groundwater lies around 1.6, and is similar to that of the Neckar, whereas uranium in fertilisers has an $\text{AU} = 1$; less than 0.01% of the phosphate goes into groundwater. Assuming a similar transport mechanism for uranium the contamination would make less than $0.004 \mu\text{g l}^{-1}$. Although uranium is apparently released in only negligible amounts to groundwater, or river water, the uranium enrichment in the ploughed and therefore well mixed upper 20–30 cm soil layer should be no higher than 1 p.p.m. and therefore almost undetectable. The lithological profile of a length of 205 m consists of a sequence of water 2–15 m deep bearing gravel horizons interbedded with clays 5–10 m thick acting as aquicludes (data from Wasserwirtschaftsamt Heidelberg). Uranium analyses on samples from the borehole core Entensee showed normal uranium contents, ranging between 1 and 4 p.p.m.

In our groundwater samples the uranium content is fairly well correlated with the HCO_3^- content. A correlation between uranium and HCO_3^- has been reported for groundwaters from a small area of the UK¹³, for the uranium content in a salt lake in California¹⁴ and for mineral waters in the Taunus area¹⁵. This correlation should presumably be attributed to the water-soluble $\text{UO}_2(\text{CO}_3)_3^{4-}$ complex with a high formation constant in a range of $\text{EH} > -0.3$, $\text{pH} > 5$ and $\log P \text{CO}_2 > -4$ (ref. 16). Most rivers meet these conditions and in fact a broad correlation also results for world rivers and lakes, including Texas rivers where a high contribution of fertiliser uranium was suggested

Fig. 2 Uranium balance for the ocean as results for an average uranium input of $0.3 \mu\text{g l}^{-1}$. U, uranium content in $\mu\text{g l}^{-1}$ or in p.p.m.; AU, activity ratio $^{234}\text{U}/^{238}\text{U}$; τ , residence time; (), refs; (+), this work.

Table 2 U content and AU of commercially available fertilisers

Fertiliser	Phosphate content	U content (p.p.m.)	AU
Kalksalpeter	Very low	0.3 ± 0.03	0.91 ± 0.1
Thomaskali	12%	3.3 ± 0.3	0.95 ± 0.1
Orgamin	6%	10.8 ± 2.0	1.05 ± 0.15
Nitrophoska-Blau	12%	48.8 ± 2.0	1.00 ± 0.04
Nitrophoska	12%	50.3 ± 2.0	1.01 ± 0.04

Only the nitrophoska fertilisers are usually applied in the Handschusheimer Feld area.

(Fig. 1). Thus the uranium content largely depends on the available HCO_3^- in the water, giving evidence that the recent uranium content in the rivers is primarily of natural origin. Differences in the bedrock material from which uranium is being leached and uranium derived from fertilisers are obviously of less importance. They might be responsible for the large scattering in Fig. 1, together with the large uncertainty of the HCO_3^- values, not contemporaneously measured with uranium. In the light of these results it seems that the low uranium content of the Amazonas is due to its unrepresentatively low HCO_3^- content and not to a lower level of anthropogenic contamination.

On the basis of this correlation we estimate the natural uranium input to the ocean, for some 35% of the supplied water, to be $0.3 \mu\text{g l}^{-1}$, in agreement with Turekian's previous estimate³. The average activity ratio of the supplied water is ~ 1.2 (refs 7, 15, 17). Applying these values to a steady-state model we calculate a residence time for uranium of 400,000 yr and an annual removal to the sediments of $10.8 \times 10^{15} \mu\text{g}$, a value some 10 times higher than when the Amazonas content is taken as the average. A roughly calculable part of uranium is deposited with the marine carbonates. The rest should then be incorporated into anaerobic sediments, which are deposited mainly on the shelf. We calculate a uranium deposition of $500 \mu\text{g cm}^{-2}$ per 1,000 yr for the entire, and $30 \mu\text{g cm}^{-2}$ per 1,000 yr, for some 6% of the shelf area. The latter is similar to the uranium-deposition rate given by Veeh for the Walfish Bay area, South-west Africa¹⁸.

We thank W. Roether for comments on the text. The borehole samples, nitrate-, phosphate- and part of the HCO_3^- data for the Handschusheimer Feld water-samples were provided by the Wasserwirtschaftsamt Heidelberg. This research was supported by the Deutsche Forschungsgemeinschaft.

Distribution of rare earth elements in some North Atlantic Kimmeridgian black shales

RARE earth element (REE) patterns of Upper Jurassic, Kimmeridgian, shales from various localities are shown here to have only minor variation in spite of deriving from very different source rocks. The formation of such uniform patterns indicate that these sediments are mature, well mixed and formed in similar depositional environments. An extension of the North Sea Kimmeridgian petroleum source rocks is indicated. Minor differences in REE patterns can be related to variations in the sand/silt content.

The REEs from La to Lu ($Z = 57–71$), have been the basis of many geochemical studies. Most of these have considered hardrock problems, but several studies have also been carried out on sediments and sedimentary rocks. Sedimentary deposits often seem to have REE distributions reflecting the different source rocks, sedimentary processes and grain size variations^{1,2}, and some of the REE distributions have been related to REE fixation in marine depositional environments^{3,4}. Generally the

Fig. 1 Reconstruction of the Arctic and adjacent areas before the lower Tertiary opening of the Norwegian Sea. Stippled lines indicate Tertiary plate boundaries. (The compilation is taken from refs 14–17). ① Wimannfjellet, Svalbard; ② Andøya, Northern Norway; ③ Well 17/11-1, North Sea; ④ Yorkshire, UK.

REEs have rather short residence time in the oceans and relative enrichment in the heavier REE (HREE) is common^{3,5}. Because HREE form complexes with higher stability than the lighter REE (LREE), LREE have a shorter residence time in seawater and may be preferentially adsorbed on clay minerals⁴. Alteration and fractionation of the REE patterns may occur in weathering horizons⁶ in addition to variation due to fixation of REE from seawater. Weathered rocks are generally enriched in total REE compared with the original unweathered rocks⁷. Of the main constituents of sediments and sedimentary rocks, the clay fraction (clay minerals and colloids mainly) contains more REE than the sand/silt fraction (rich in quartz and feldspars)⁸. Separations of different sedimentary fractions, either by varying depositional conditions or by weathering reactions may lead to fractionation of the REEs.

REE analyses are normally presented in 'comparison diagrams' (ref. 9), where the elements analysed are all related to a reference distribution. Sedimentary and metamorphic rocks are generally compared with proposed upper crustal average, based on composite sample of 40 North American Shales (40 NAS)^{2,10}. The samples analysed here have been correlated

with this composite sample. The individual element/element ratios have been plotted on a logarithmic scale against atomic number (Fig. 2).

The present work was designed to study how different source rocks affect the REE compositions of the sediments of shallow marine depositional regimes. Radiochemical neutron activation analyses (RNAA) were carried out on 22 samples from the following localities (Fig. 1): Svalbard, Wimannfjellet; Northern Norway, Andøya; North Sea, Well 17/11-1, Norwegian sector; UK, Yorkshire. The method used is based on USGS standards G2 and BCR 1, using the recommended values of Flanagan¹².

In Upper Jurassic Kimmeridgian times similar depositional regimes existed in these four areas (Fig. 1). The four sections represent original different positions in the rather shallow epicontinental Kimmeridgian sea. However, different source rocks were exposed in the adjacent areas. The sediments deposited were generally dark, marine, organic-rich clays, although those on Andøya were somewhat more sandy/silty than in the other localities.

Eight (La, Ce, Nd, Sm, Eu, Tb, Yb, Lu) of the REEs have been determined (Table 1), distribution patterns are shown in

Fig. 2 *a, b*, Comparison plots of the REE content in Kimmeridgian shales from Wimannfjellet (Svalbard). *c*, Comparison plot of the REE content in Kimmeridgian shales from Andøya (Northern Norway). *d*, Comparison plot of the REE content in Kimmeridgian shales from well 17/11-1 (North Sea). The hatched area shows variation area for the six samples indicated, with triangles marking the extreme ratios for the different elements. *e*, Comparison plot of the REE content in Kimmeridgian shales from Yorkshire (England). The hatched area shows variation area for the five samples indicated, with triangles marking the extreme ratios for the different elements. All the REE patterns in this figure are plotted after Coryell *et al.*⁹ and normalised to the composite of 40 North American Shales (NAS), with values from Haskin *et al.*¹⁰.

NAS is a composite of 40 North American Shales values from Haskin *et al.*¹⁰.

Fig. 2. The patterns of the different samples are very similar. In spite of deposition at different localities and derivation from different sources, no major variations in the REE distributions are found (Fig. 2). This probably reflects rather extensive weathering, repeated reworking and homogenisation of sediments before final deposition as fine-grained silts and clays. The sample sets from the four different localities generally show minor enrichments in LREE. This may be due to minor selective adsorption of LREE on weathered clay minerals in the seawater.

In detail the samples from Yorkshire (Fig. 2e) and the North Sea (Fig. 2d) have higher total REE contents and show enrichment of LREE compared with samples from Andøya (Fig. 2c) and Svalbard (Fig. 2a, b). This correlates with certain mineralogical differences—the sediments in Yorkshire and the North Sea being generally fine grained, containing less quartz and feldspar. Higher sand/silt concentrations in the Andøya samples have served to dilute the samples which have lower REE concentrations.

The Svalbard samples analysed are, based on their REE distribution patterns, divided into two different populations (Fig. 2a, b). A selective leaching of the middle REEs due to diagenetic processes is the only explanation we can propose for this observation.

In Svalbard, Andøya and North Sea areas the Upper Jurassic transgression¹³ is reflected in a progressive increase in finer material towards the top of the Kimmeridgian. These developments are partly seen in an upwards increase in total REE and in lower LREE/HREE ratios, reflecting influx and deposition of finer-grained material with lower percentage of sand and silt. However, the similar REE patterns in the different localities clearly indicate rather persistent depositional conditions. Only sample 7140 in the North Sea sample set and sample D 138 from the Andøya sample set seem not to conform. These variations may be explained by occurrences of dolomite in D 138 which is not detected in the other Andøya samples, while sample 7140 from the North Sea have higher sand/silt and lower carbonate contents than other samples from that locality.

Strong weathering of source rocks and later reworking of weathering products resulted in deposition of marine clays with rather similar REE distribution patterns in the different localities, in spite of derivation from different source rocks. This

shows rather similar and persistent depositional regimes in the huge Kimmeridgian epicontinental sea and may indicate possibilities for Kimmeridgian petroleum source rocks north of the North Sea. The generally weak LREE enrichments point towards selective LREE adsorption on clay minerals in seawater. Minor variations in the REE concentrations may be due to grain size variation which in turn reflect minor differences in sedimentation conditions in the Kimmeridgian epicontinental sea.

The Andøya samples were provided by A. Dalland; J. Nagy provided the Yorkshire samples and the Norwegian Petroleum Directorate those from the North Sea. The project is supported by the Norwegian Petroleum Directorate.

Losses of nitrous oxide dissolved in drainage water from agricultural land

DISCUSSIONS on the fate of nitrogen in soil usually assume that the gases produced by denitrification—nitrous oxide and molecular nitrogen—are lost only by movement in the gaseous phase towards the soil surface, where they escape to the atmosphere. As far as we know, there are no published reports of the transport of these gases dissolved in water draining from agricultural land. However, the anaerobic conditions necessary for denitrification develop to an appreciable extent in drained agricultural soils when the soil water potential is zero or positive¹⁻⁶; there is then likely to be drainage of water through the soil. In the soils of southern England, nitrous oxide can be found for extended periods during the wetter months^{7,8}, where there is on average ~250 mm rainfall in excess of evapo-transpiration and soil storage⁹. As nitrous oxide is fairly soluble in water (1.0 ml gas per ml water at 5°C) we have examined the possibility that significant quantities are transported from the soil in drainage water. We report here for the first time observations that nitrous oxide can be lost from the soil by leaching in amounts comparable with those lost in the gas phase from the soil surface.

Water issuing from agricultural drains in heavy clay soils (Table 1, site 2 Lawford (Rowsham) series¹⁰, sites 3 and 4 Denchworth series¹¹) contained much more nitrous oxide than was present in rainfall. Appreciable concentrations of nitrous oxide were also found in water draining from lysimeters containing intact columns (80 cm diameter and 135 cm deep) of two other fine textured soils (Salop¹¹ and Bromyard¹² series). Laboratory incubation experiments showed that the denitrifying activity of drainage water was negligible, even when nitrate and

glucose were added in anaerobic conditions (unpublished results). The nitrous oxide in drainage water had, therefore, come from the soil and not from biological activity in water as it passed down the drain. In addition to water from agricultural drains, appreciable concentrations of nitrous oxide were found in samples from streams, a lake and domestic water supplies (Table 1), but some of the nitrous oxide contained in these sources may possibly have been produced after the water had emerged from the drains (for example, as a result of microbial activity in bottom sediments¹³).

A preliminary estimate of the quantity of nitrous oxide that might be contained in drainage from our experimental fields can be made by assuming that all the excess of rainfall over evapo-transpiration during the winter months (November to March inclusive), on average about 250 mm of water, was removed from the soil by the tile drainage system, and that also this drainage contained a concentration of 100 $\mu\text{g N}_2\text{O-N l}^{-1}$; the amount of nitrogen leached as nitrous oxide would then be about 0.25 kg ha^{-1} , but greater rates of loss may be expected during short periods of high rates of denitrification and drain flow. In comparison the fluxes of nitrous oxide gas from the soil surface in winter, measured at the same sites and during the same period as those in drainage were equivalent to 0.15–0.9 kg N ha^{-1} (ref. 14). Losses as molecular nitrogen in the gas phase from the soil surface may be considerably greater than this, as it is commonly believed¹⁵ that the ratio of $\text{N}_2:\text{N}_2\text{O}$ is ~16:1. However, leaching losses of molecular nitrogen greater than that of nitrous oxide are unlikely because the solubility of nitrogen in water is 50 times less than nitrous oxide (0.02 ml gas per ml water at 5°C) and it would therefore require an unusually high $\text{N}_2:\text{N}_2\text{O}$ ratio of 50:1 or more to achieve comparable rates of loss. For comparison, the concentration of nitrate-N in drainage water always exceeded the concentration of dissolved nitrous oxide-N by 1–3 orders of magnitude (Fig. 1).

Water samples collected from an open drain outlet, as in the present work, provide an inaccurate basis for estimating the amounts of nitrogenous gases leached from the soil, as an

Fig. 1 Nitrous oxide (solid bars) and nitrate (points) content of water draining from an arable field during the winter of 1977–78 at Compton Beauchamp, Uffington, Oxfordshire. The field was sown with winter wheat in October 1977; no nitrogen was used until April 1978 when 80 kg N ha⁻¹ as ammonium nitrate was applied. The rainfall between November 1977 and May 1978 was 440 mm (the long term average for this period is 405 mm).

unknown amount of gas diffuses from the water or soil into the atmosphere of the drain. Air drawn from drains contained nitrous oxide concentrations of up to 100-fold that in the terrestrial atmosphere, but neither measurements nor estimates of loss by gas movement in drains have been made. However, improved estimates of leaching losses of nitrous oxide made during a number of contrasting winters may be obtained from a long term field experiment, begun in 1978, where the equipment for the continuous monitoring of water is designed to prevent the gas phase transport of nitrous oxide from the drain.

Although in our preliminary experiments the loss of nitrogen from the soil profile by nitrous oxide dissolved in drainage water seemed a minor component of the soil nitrogen balance, in other conditions losses by this route could be larger, particularly where high rates of denitrification and drainage of water are experienced. However, the loss of nitrous oxide in drainage from agricultural land is an important new factor to be considered in assessments of the contribution made by denitrification to the nitrous oxide content of the atmosphere.

Developmental fate of the cyanogenic glucoside linamarin in Costa Rican wild lima bean seeds

WHEN a seed germinates, we expect the defensive secondary compounds it contains to be transferred intact to the growing seedling, or variously decomposed to produce resources for the growing seedling. The seeds of wild indigenous Costa Rican lima beans (*Phaseolus lunatus* L.) contain about 3.45% fresh weight of linamarin¹, a cyanogenic glucoside that can enzymatically decompose to produce 0.37% fresh weight hydrocyanic acid (HCN). We report here that, after germination, the amount of linamarin in the total seedling (roots, cotyledons, and shoots) remains essentially constant during a 26-day experimental period and moreover corresponds to the amount of linamarin present in the seed before germination (Fig. 1).

To determine the fate of this defensive secondary compound in young seedlings, we germinated seeds and monitored the linamarin content of the seedlings for 26 days. While the amount of linamarin per seedling remained constant, the distribution of the glucoside present initially only in the seed changed dramatically with time. For example, after 6 days 42% of the total linamarin in the seedling was contained in the cotyledons, 27% was in the new leaves and shoot tip, 20% was in the stem and 11% was in the roots. After 14 days, 69% of the linamarin was in the leaves, and after 16 days the cotyledons were devoid of linamarin and dropped off. The change in fresh weight of the different plant parts, expressed as per cent of the plant's total weight, paralleled the change in linamarin for each different part. That is, the cotyledons decreased in weight each day by an

Fig. 1 The linamarin content of individual seeds or seedlings of wild lima beans (*Phaseolus lunatus*). Seeds were germinated by pricking the thin seed coat with a pin and soaking overnight in distilled water. Seedlings were grown in vermiculite at 24 °C with a 14-h photoperiod. On the 7th day of growth the cotyledons were carefully removed from 15 seedlings (○) to permit comparison with untreated seedlings (●) whose cotyledons remained on the plant for ~2 weeks. Linamarin content was determined by grinding weighed fresh seeds or seedlings in liquid nitrogen with a mortar and pestle. The ground sample was immediately transferred to 2 ml of 0.1 M phosphate buffer (pH 6.8) containing the enzymes emulsin and linamarase in the outside compartment of a centre well flask; the centre well contained 1 ml of 1 M NaOH. After 24 h in a shaking water bath at 37 °C, the contents of the centre well were assayed for HCN, a product of the enzymatic decomposition of linamarin. The method used⁶ detects HCN in the range 0.01–0.15 µmol. Qualitative examination of 80% (v/v) ethanolic extracts by gas liquid chromatography⁷ established that linamarin was the only cyanogenic glycoside present either in seed or seedlings. Seeds were hand-shelled from mature dry pods from a large wild plant in March, 1976 at Finca La Parca, Cañas, Guanacaste Province, Costa Rica. An average of 62 mg (s.d. 13 mg, n = 25). Seeds from this morphic; 60% were black and 30% brown. The black seeds were used in the

amount corresponding to 5% of the total weight of the seedling and lost 4.4% of the total linamarin each day. Roots gained 2% in weight and 0.5% in linamarin each day while stems lost 0.9% in weight and 0.4% in linamarin each day.

The data displayed in Fig. 1 suggest that the plant either transfers its linamarin intact from the seed (cotyledons) or breaks it down and resynthesises it in equal amounts during new growth of the seedling. To determine what happens, the cotyledons were removed from 15 plants after 7 days of growth. The excised cotyledons contained approximately 4.5 μmol linamarin, and the glucoside content of the seedlings dropped to about 4.0 μmol per plant. Although the treated seedlings continued to grow and develop, their linamarin content remained constant throughout the experiment. This could be explained by assuming that the plant uses only the breakdown products of the linamarin for resynthesis in the growing seedling. However, the breakdown products of the aglycone of linamarin are acetone and HCN, compounds which are not readily converted to valine, the demonstrated primary precursor of linamarin in other linamarin-containing species¹. We therefore prefer the more parsimonious explanation that the linamarin is transferred intact from the cotyledons to the growing seedling.

The degree to which plants synthesise secondary compounds as they change and develop, as opposed to shifting the location of compounds already synthesised, should be an important consideration in the pattern and budget of chemical defenses against herbivores. In *Heteromeles arbutifolia*, a chaparral evergreen shrub in California, the cyanogenic glucoside in the immature fruit is transferred to the ripening seed, and thus the same chemicals probably serve as a defence in consecutive developmental stages². On the other hand, seeds of *Sorghum vulgare* do not contain a cyanogenic glucoside but the seedlings synthesise large amounts of it (dhurrin) in the first 5 days of growth³. Some kinds of secondary compounds are probably removed from deciduous tree foliage before the leaves are shed; presumably they can be used in other parts of the plant or in leaf production in later seasons.

Seeds contain a large variety of secondary compounds which are undoubtedly defensive for the seed⁴, amongst other possible functions. While it is easy to postulate that such secondary compounds are stored as resources for developing seedlings, this has never been demonstrated. In the present study we have demonstrated that they may also be defense resources for the developing seedling. In short, if the seed is a container whose volume or weight is to be minimised (for dispersal purposes), the parent plant produces a higher quality package for the seedling if it puts the intact, defensive molecule into the seed than if it puts in the raw materials for synthesis of that molecule.

With this view in mind, there are at least three selective forces acting on the quantity of a given kind of secondary compound to be found in a seed. First, there are the levels that the parent plant can donate considering the total number of seeds it is producing and its own needs. Second, there are the levels necessary to deter the relevant herbivores from eating the seeds. Third, there are the levels needed to give enough defensive compounds to the seedling to meet its herbivore challenges. The first selective force will act to minimise the compound level and the second two to maximise it; however, the second two need not necessarily have the same optimal level. For example, co-evolutionary selection by a bruchid beetle known to feed on lima bean seeds (D.H.J., unpublished) may drive the concentration of linamarin in the seed up until it is higher than that which is needed by the seedling. At this point, the levels of linamarin in the seedling may have increased to a point well over that which is needed to deter an insect that eats seedling leaves. Conversely, strong selection on the seedling for increased linamarin content by a defoliator may drive the linamarin content of the seed to a high enough level that the bruchid larvae can no longer survive on the seed. This would be a real-life example of the theoretical model in which herbivores competitively interact through the resource budget of the plant in evolutionary

Somatic fusion between cell wall mutants of *Chlamydomonas reinhardtii*

SOMATIC FUSION has recently been used to isolate hybrids from auxotrophic mutants of fungi^{1,2}, yeast³ and mosses^{4,5}. These fusions were performed by using polyethylene glycol (PEG) and/or CaCl_2 solutions on protoplasts which were prepared from cells of tissues treated with enzyme mixtures to dissolve the cell wall. In the unicellular green alga *Chlamydomonas* mutant strains unable to make a cell wall have been isolated^{6,7}. Such mutants, similar to plant protoplasts prepared by enzymatic digestion, can be easily grown in defined liquid or agar media⁸. However, they differ from true protoplasts in that they do not burst in hypotonic medium or even in distilled water, indicating that some mechanism of osmoregulation is present⁶. It was thus of interest to determine whether these cell wall mutants could be used as plant protoplasts in fusion experiments. We report here the isolation of stable fusion products

Table 1 Comparison of four fusion products from 303 $\times$ 308 with the wild-type haploid strain and a diploid *arg-7* $\times$ *arg-7-3* obtained by sexual mating

Strain	Mating type	Cell volume* (μm^3)	Nuclear volume† (μm^3)	Relative DNA content§		Chloroplast DNA (% of total DNA)
				1	2	
Haploid (WT)	+ or -	30 (± 5)	2.8 (± 0.5)	1.0	1.0	14.1
Diploid (<i>arg-7</i> $\times$ <i>arg-7-3</i>)	-	58 (± 10)	6.9 (± 1.9)	1.9	1.9	11.1
303 $\times$ 308/1	+	58 (± 10)	7.1 (± 1.2)	1.8	2.0	7.3
303 $\times$ 308/2	+	56 (± 10)	-	-	-	-
303 $\times$ 308/3	+	56 (± 10)	7.6 (± 1.4)	-	-	-
303 $\times$ 308/4	+	60 (± 10)	-	-	-	-

* Cells grown on agar medium were suspended in distilled water and incubated overnight in the dark before being measured. The volumes were determined with a Coulter electronic counter model ZF (orifice 100 μm).

† Cells grown on agar medium were fixed and stained for nuclei (Feulgen reaction). The nuclear volumes were determined from diameter measurements of 20 nuclei after photographic magnification, assuming that nuclei were spherical.

§ Cells were grown in 300 ml of liquid medium and collected during exponential growth. 1. The DNA was estimated by the diphenylamine reaction (modification of the Burton's method). Values are means of two experiments. 2. Cells were incubated overnight in distilled water then fixed in alcohol. They were treated with RNase for 1 h (1 mg ml⁻¹ at 37 °C) and labelled with propidium iodide. The DNA content was measured by flow microfluorimetry.

|| The cells were grown in 1 l of liquid medium. They were lysed with SDS (10% final concentration) and then DNA were extracted by successive digestions with pronase, RNase and proteinase K, interspersed with alcohol precipitations¹³. The DNA were further purified on agarose¹⁴ and ultracentrifuged in CsCl gradients. Nuclear ($d = 1.724 \text{ g cm}^{-3}$) and chloroplast ($d = 1.695 \text{ g cm}^{-3}$) were clearly separated and analysed by UV spectrophotometry.

Fig. 1 Ultra-thin sections through cells of 303 (a) and 308 (b) strains lacking a cell wall. The cells were fixed with 4% glutaraldehyde in 0.1 M sodium cacodylate buffer, pH 7.0, for 1 h, post-fixed in 2% osmic acid for 2 h. The samples were dehydrated through an alcohol series and embedded in Epon. Sections were stained with uranyl and lead. Scale bar, 1 μ m.

obtained from cell wall haploid mutants of *Chlamydomonas reinhardtii* having the same mating type (mt^+) and bearing genetic markers of auxotrophy.

The two following strains, isolated after crosses between mutants available in our laboratory, were used in the fusion experiments: strain 303, mating-type plus (mt^+), absence of cell wall ($CW15$)⁶, auxotrophy for arginine ($arg-7$); strain 308, mating-type plus (mt^+), Cw_d (a putative cell wall strain defective for four phosphatases and called $P_2P_dPD_dPD_d$ by Loppes and Deltour⁷), auxotrophy for arginine ($arg-7-3$). The $arg-7$ and $arg-7-3$ mutants, both defective for the same enzyme and mapping in the same cistron are able to complement and restore the wild phenotype in diploids⁹.

Analysis of the strains 303 and 308 under the light microscope revealed that both were deprived of a cell wall. The absence of wall was confirmed in electron microscopy (Fig. 1).

A complementation test made between the strain 308 mt^+ and a strain identical to 303 but mt^- led to recover prototrophic diploid cells with a normal cell wall. This indicates that $CW15$ and Cw_d mutations do complement and are probably located in different genes.

The mt^+ cells used in the fusion experiments were routinely grown on agar mineral medium deprived of ammonia and enriched with yeast extract (M-N + YE¹⁰), containing enough arginine to allow growth of the auxotrophs. Several assays were

conducted by treating the cells in PEG solutions for 30 min, then washing them and plating on minimal agar medium. Positive results were obtained in two experiments and negative results in several others. We finally obtained reproducible positive results by using the following simple method. About $4-7 \times 10^7$ cells of each strain were sampled with a platinum loop and transferred onto a minimal agar medium¹¹ in Petri dishes (9 cm diameter). The cells were mixed with a loop, then 0.1 ml of the following fusion solution was added: 50 mM PEG 6000 Merck, 7.5 mM $CaCl_2$, 5 mM glycine, NaOH to make pH 8.0. This solution was sterilised by filtration through a Millipore membrane (0.45 μ m). The cells were carefully mixed in the fusion solution then spread on the agar surface. Two types of control were made: (1) each strain was separately treated with the fusion solution; and (2) a mixture of the two strains was treated with distilled water. After an eight-day growth at 25°C 8,000 lux, 30-100 colonies ranging between 0.2-1.2 mm diameter were observed in the plates corresponding to the fusion treatment. No colony was observed in the controls.

Four colonies were isolated and subcultured for further analysis on medium deprived of arginine. A microscopical observation of the four isolates revealed the presence of a cell wall in all of them. This observation was confirmed by electron microscopical analysis (Fig. 2). The fusion products form a wall as do the diploids obtained by sexual mating.

Fig. 2 Ultra-thin sections through cells of a fusion product 303 $\times$ 308/1 (a) and a diploid $arg-7 \times arg-7-3$ (obtained by sexual mating) (b). The cell wall is present (arrow). The samples were prepared for electron microscopy as described in the legend to Fig. 1. Scale bar, 1 μ m.

The fusion products were compared to the wild-type haploid strain and to a diploid strain (*arg-7* × *arg-7-3*) obtained by sexual mating: they were analysed for their cell volume, nuclear volume, total DNA content and chloroplast DNA: total DNA ratio. The results (Table 1) indicate that the fusion products are very similar to diploids as far as cellular volume, nuclear volume and DNA content per cell are concerned. The fusion product 303 × 308/1 (the only one analysed for that criterion) has however a lower chloroplast DNA content (7.3% of total DNA) than that of the haploid or diploid strains (14.1 and 11.1%). Chiang¹⁵ and Lane and Sager¹⁶ found that vegetative haploid cells contain about 14% chloroplast DNA whereas gametes contain only 7%. We do not know whether the low value found for the isolate studied here corresponds to a peculiarity of the strain or if it is a common feature of the fusion products. This point will be further analysed.

The fusion products were, moreover, found to be mating type plus (Table 1): they differ in that respect from diploids obtained by sexual mating which are always mating type minus (*mt*⁻ gene is dominant over *mt*⁺). The four strains were crossed with gametes of haploid wild type *mt*⁻. Zygotes were visualised in all crosses, indicating that the four strains were fertile. The zygotes issued from two crosses were plated on minimal medium containing 4% agar and matured in the dark⁴⁷. The unmated cells were killed by exposure to chloroform vapour and after germination of the zygotes the meiotic products were plated on a rich agar medium (M-N+YE). The colonies developed after 10 days were replicated on rich (M-N+YE) and on poor (M) medium. In both crosses, wild type colonies and some colonies able to grow on rich medium only were detected. Analysis of these auxotrophs showed that they specifically required arginine for growth. This indicates that the two strains analysed were still bearing *arg*⁻ markers.

These results demonstrate that somatic fusion is possible with cell wall mutants of the same mating type (*mt*⁺) in the green alga *Chlamydomonas reinhardtii*. The fusion products are very similar to diploids obtained by sexual mating but differ from them by their mating type and perhaps also by their chloroplast DNA content. They constitute new tools to improve our knowledge of problems such as the maternal inheritance of chloroplast genes or the gene dosage effects in mating-type expression. The present results also open new possibilities for the isolation of hybrids between different algae species.

We thank Mrs A. Miller-Faures for the determinations of DNA content by flow microfluorometry.

Genetic analysis of maternal information in *Drosophila*

EMBRYONIC development is controlled by the information carried by the gametes of the zygote's parents. However, although the chromosomal information is similar in both gametes the oocyte also provides a structural frame (determining embryonic axes), determinants in the cortex and a metabolic pool to support early embryonic events (see ref. 1). The active transcription of thousands of DNA loops in the lampbrush chromosomes of amphibian oocytes suggests that the egg contains transcripts of a large fraction of the genome². In sea urchin oocytes the mRNA complexity might account for the synthesis of several thousands of different protein species^{3,4}. Genetic analysis should help to establish the functional meaning of the information present in the oocytes for embryonic development. In this study we have analysed the effect of chromosome deletions on the development of *Drosophila* embryos. The results indicate that the products of a large proportion of the maternal genome, present in the oocyte, are sufficient and necessary for epidermal morphogenesis and differentiation in the embryo.

In *Drosophila* about 90% of the genes have lethal alleles⁵, and about 30% of those lethals die in the homozygous condition in embryonic stages⁶. The lethal effective phase (LEP) of most of these mutants is late—after completion of morphogenesis and sometimes even after completion of epidermal differentiation⁷. Lethal mutations caused by chromosome deletions may show earlier LEPs, possibly because they have a higher probability of including null-alleles of early acting genes^{7,8}. However, it is not known how far the LEP of the embryos is due to the actual genetic constitution of the zygote or to insufficient supply of gene products from the heterozygous mother to the oocyte.

The chromosome deletions used in this study were previously defined as being homozygous cell lethal in clones of adult epidermal cells resulting from mitotic recombination⁹. This cell lethality implies that products of the genes contained in the deletion are necessary for cell division and/or cuticular differentiation. These deletions might therefore be expected to prevent cell proliferation and cuticular differentiation in homozygous embryos. In this study we analyse the lethality of embryos from parents both of which are heterozygous for chromosome deletions (HM cross) compared with that of embryos from heterozygous mothers but wild-type fathers (♀ HT cross) or from heterozygous fathers but wild-type mothers (♂ HT cross). Whereas the first cross gives rise to homozygous (25%) and heterozygous embryos (50%) the second and third cross yields only heterozygous embryos (50%). As all the deletions studied are recessive lethals, heterozygous embryos are expected to show normal morphogenesis and differentiation.

To avoid lethality due to deleterious factors present in the rest of the genome the experimental crosses were made with F₁ flies from an outcross of the deletion-carrying stock to a wild-type (Vallecas) stock. Females were maintained with an excess of males for 3-4 d in rich medium and afterwards transferred every day to an egg deposition chamber for 3-4 h. Eggs were counted after removal of the parents. After 24 to 26 h (embryonic development takes 21-22 h) the unhatched eggs were counted, dechorionated in sodium hypochlorite (7%) and observed under paraffin oil under a compound microscope. Samples of these eggs were mounted in Faure's medium. We have classified the LEPs of dead embryos as before any visible cuticular differentiation (before stage 9 of Bownes¹⁰) or with clear segmentation and cuticular differentiation of mandibles, tracheae, dorsal and ventral bands of hooks (stage 14). Dead embryos between stages 9 and 14 occurred in less than 10% of all crosses studied. Samples of eggs from each cross were studied 4-6 h after laying to check that all had initiated development. We have made no

Fig. 1 Per cent of lethal embryos and embryonic lethality phase (LP) in crosses of flies carrying chromosome deletions. LP, percentage of lethal embryos which reach stage 14 (ref. 10). Deletions of X(□), 2nd (○) and 3rd (△) chromosome (deletions described in ref. 9). Open symbols indicate deletions which are not viable in clones of epidermal cells; full symbols viable ones⁹. HM, cross of heterozygous mothers to heterozygous fathers (for deletions in X, males are wild-type). ♀ HT and ♂ HT, crosses where either the female or the male were deletion heterozygotes, crossed to wild-type flies. Percentages of lethal embryos based on 5–10 laying periods and 400–1,200 eggs. Arrows, expected lethal fraction in the HM cross and in wild-type control flies. Connecting lines between representative deletions in the three crosses.

attempt to determine the phenocritical phase⁶ (earliest mutant effects) of these deletions (see below) nor how they affect morphogenesis of internal organs.

For the various crosses the numbers of lethal embryos and their LEPs are presented in Fig. 1. In the HM cross the proportion of lethal embryos varies around the expected 25%. Lower values indicate that some of the homozygous embryos are capable of hatching as larvae and should die in subsequent developmental stages. Higher values indicate that not only homozygous embryos but also other sibling embryos (heterozygotes or even wild type) die. Surprisingly, in most of the deficiencies studied the embryos reach stage 14 (Fig. 1). They show normal cuticular segmentation and differentiation as well as malpighian tubules and even active movements. These findings indicate that gene products which are essential for epidermal cell proliferation and for cuticular differentiation in imaginal disks must either have been available from the oocyte or are not required for embryonic development.

The following data indicate that maternal gene products are necessary for early development. In 8/17 ♀ HT crosses embryonic lethality is significantly higher than in wild-type controls (2%) (Fig. 1). This lethality could result from the genetic insufficiency of deletion heterozygous embryos. However, the lethality found in the ♂ HT cross, which gives rise to the same

heterozygous embryos is, in 8/17 of the deletions studied, lower than in the ♀ HT cross (Fig. 1). Thus, the lethality in embryos from deletion heterozygous mothers must be due to the haplo-insufficiency of the genes included in the deletion chromosome in the oocyte. Lethality phase data for embryos from the ♀ HT cross support that inference: these embryos die mainly in the early stages of development. This suggests that, for some of the zygotes, the chromosomal information is not expressed in time to rescue the oocyte insufficiency. Embryonic lethals usually show several lethal phases⁷, so it is possible that the different LEPs found in embryos of the HM cross actually correspond to the effect of either maternal or zygotic insufficiency.

We have studied 29 deletions in the major chromosome arms, extending from 2 to 30 salivary chromosome bands⁹. The total number of deleted bands studied is 342, of which 283 are not overlapping. The latter figure corresponds to about 6% of the total number of bands (5,000) in the polytene chromosomes. If the chromosome regions analysed are considered as a representative sample of the genome, several general conclusions can be drawn. There is a poor correlation between the size of the chromosome deletions and embryonic lethality in the HM cross ($R=0.35$) or in the ♀ HT cross ($R=0.32$), supporting the conclusion^{7,8} that lethality does not result from additive effects of the deleted genes. More than 50% of the homozygous

embryos of all the deletions studied reach advanced stages of embryogenesis, including normal segmentation and cuticular differentiation. To that group four *minute* loci studied and the *nullo-IV* embryos¹¹ should be added. Thus, for epidermal derivatives it seems that embryonic morphogenesis and differentiation can proceed in the absence of many genes including those necessary for the viability of epidermal cells in imaginal anlagen. Both developing systems, embryo and imaginal anlagen, differ in that whereas the imaginal anlagen undergoes extensive cell proliferation during the larval period, cell proliferation in the embryo following blastoderm is minimal^{12,13}. Thus enough maternal gene products (mRNAs or proteins) may perdure in embryonic cells to allow normal segmentation and cuticular differentiation. If this interpretation is correct then there are two important corollaries.

Lethals with phenocritical phases⁶ in post-embryonic stages or affecting particular tissues cannot be used to indicate the existence of specific genes for larval or imaginal development or specific tissues. It is possible that a large fraction of genes are transcribed in the oocyte and active in embryonic as well as in other developmental stages and in several tissues, but have different perdurance periods. The difficulty of ascertaining phase and tissue specificity of genes is increased when we know only their leaky mutant alleles.

Mutant alleles with phenotypes in the progeny of homozygous mothers (maternal-effect mutants) are known in a small fraction of the genetic loci^{14,15}. Some were shown to be allelic to homozygous visible mutants, others to express the phenotype only at restrictive temperatures. The study of their null-alleles will help to distinguish maternal information genes proper from genes with pleiotropic effects during development and oogenesis.

If embryonic morphogenesis, at least for cuticular segmentation and differentiation, can proceed without the zygotic contribution of an important fraction of the genome, how is it achieved? Systematic study of deletions in lethal embryos may show which genes are responsible for structural elements and which are involved in the specification of segments¹⁶, germ layers and tissues. The haplo-insufficiency shown by some deletions in heterozygous mothers should help to distinguish morphogenetic effects assignable to the female gamete from those which result from the zygotic constitution and only appear in homozygous embryos.

We thank Mrs B. Sanchez Saez for technical assistance, Drs P. A. Lawrence, R. Nöthiger and T. R. F. Wright for critically reading the manuscript and the CADC and Rodriguez Pascual Foundation for support.

Meiotic crossing over exchange in the female mouse visualised by BUdR substitution

ALTHOUGH chiasmata have long been thought to be sites of crossing over exchange between chromosomes during meiosis, in keeping with the partial chiasmatype hypothesis^{1,2}, there has been no convincing visual evidence of this despite many attempts (summarised in refs 3-6). Taylor⁷ confirmed by autoradiography that meiotic crossing over occurs by exchange involving breakage and reunion of chromatids. However, because of the poor resolution of autoradiography, requiring study of meiotic chromosomes after 1st metaphase, and because of interference by sister chromatid exchanges, a one-to-one correspondence between chiasmata and exchanges of labelled chromatid segments could not be established^{8,9}. The difficulty was alleviated by correlating chiasmata and exchanges with temperature variation¹⁰, or by selecting a species with localised chiasmata and thus with predictable points of exchange¹¹. 5-Bromodeoxyuridine (BUdR) substitution with differential labelling and consequent differential staining of mitotic chromosomes¹²⁻¹⁵ offer the potential for studying chromosomes at 1st meiotic metaphase, giving an unequivocal picture and separating sister chromatid exchanges from chiasma exchange points between homologues. Tease¹⁶ has reported success with male grasshopper meiotic chromosomes, but an attempt with the male mouse showed only sister chromatid exchanges in the sex chromosomes, and the autosomal bivalents at 1st meiotic metaphase were not differentially stained¹⁷. In the male Armenian hamster the sex chromosomes showed differential staining and an apparent exchange of segments but again the autosomes were not critically differentially stained¹⁸. This may be partly due to the make-up of the male meiotic chromosomes. We have overcome these problems by using an *in vitro/in vivo* technique¹⁹ which enables us to expose the differentiating germ cells of embryonic ovaries to BUdR *in vitro* and to collect and

Fig. 1 14-Day (plug = 1) embryonic ovaries were set up in culture on agar strips in Ham F10 (Gibco Biocult) plus penicillin/streptomycin, L-glutamine, 20% calf serum and 3 μ M deoxycytidine, with ³H-BUdR, 0.1 μ Ci ml⁻¹ (0.5 Ci mmol⁻¹). After 48 h they were transferred to basic medium without ³H-BUdR, and transplanted on day 8 of culture (setting up day 0), with minimum light throughout. Meiotic preparations from ova were collected on day 19 (transplant day 0). Autoradiography was carried out after stripping film application and 6 weeks development (photographed Kodak 5460, linear magnification $\times 800$).

Fig. 2 14-Day embryonic ovaries were cultured in basic medium with cold BUdR, $2.0 \mu\text{g ml}^{-1}$. After 24 h this was changed to basic medium without BUdR. They were transplanted on day 8 and ova were collected on day 19. The cells were stained with Hoechst fluorochrome and examined by differential fluorescence in a UV light microscope. They were then exposed to daylight for 3 d, stained with 10% Giemsa (Gurr) in phosphate buffer, pH 6.8, and mounted in Xam (for details see legend to Fig. 1; linear magnification $\times 800$). *a*, 1st meiotic metaphase with differentially labelled chromatids. *b*, Meiotic configuration selected from *a*, with diagrams (see text). Heavy and light lines reflect the pattern of BUdR substitution; circles represent centromere positions. Note that in *v* an exchange between homologues has occurred very near the centromere.

display the chromosomes²⁰ of the mature oocytes some time after transplantation into young spayed adults. We report our results here.

We used A Strong female fetuses as donors and CBA/H-T6T6 females as recipients, and were completely successful, but in general it is known that even in conditions similar to ours ovarian isografts fare better than allografts²¹. By chase-labelling germ cells *in vitro* with ^3H -thymidine, followed by autoradiographic scoring at pachynema/diplonema 4 d later, we established the optimum time for BUdR labelling in our system and strain.

Using ^3H -BUdR we were able autoradiographically to ascertain its presence in most 1st metaphase chromosomes (Fig. 1). Subsequent use of the minimal concentration of BUdR which gave differential staining of mitotic chromosomes, enabled us to obtain such staining of the meiotic chromosomes in our system. Because of the distinctive differential staining of the chromatids (light chromatids have more BUdR than dark ones) label segregation can provide critical information even at 1st meiotic metaphase (Fig. 2*a*), thus obviating some of the problems with autoradiography. All three types of side-by-side chiasma formation are observed (Fig. 2*b*, dark to dark: i; dark to light: ii, etc.). Two configurations (Fig. 2*b*, *v*, *ix*) of the displayed cell show the points of crossing over and one of these also shows an interstitial sister chromatid exchange (Fig. 2*b*, *v*). In two of the three 'crosses' (Fig. 2*b*, *vii*, *viii*, the latter of which is undergoing separation of homologues) the point of exchange corresponding

to the single chiasma is not detectable, and these crosses can be interpreted as being derived from exchanges between equally labelled homologous chromatids (Fig. 2*b*, *i* or *iii* and *iv*). It is also interesting that one of the configurations (Fig. 2*b*, *vi*) shows a three-strand double involving proximally two dark chromatids and distally a dark and a light one. The latter we interpret as a resolved chiasma; we can therefore detect the point of distal exchange in the two homologous chromatids. In an unlabelled metaphase preparation the latter crossover point would have been undetected.

Our data do not indicate whether or not chiasmata are terminalised in the mouse, or at least in the female of the species. Tease¹⁶ found that there is no terminalisation in the male desert locust. The issue of terminalisation⁵ is relevant both theoretically (assessment of chiasma and crossover frequency) and practically (alleged factor in maternal-age-dependent non-disjunction in mammals²²).

In conclusion, this is the first demonstration of partial chiasmamtypy with crossover exchange, and its unequivocal relation to chiasmata, in a female mammal, by an *in vitro/in vivo* technique which is very versatile in the investigation of other problems of mammalian female meiosis.

This work was supported by the Spastics Society and by a grant from an anonymous donor, whom we thank together with Dr F Giannelli who advised on autoradiography.

Movement of microorganisms in viscous environments

SOME microorganisms swim well in solutions containing viscous agents (molecules with long unbranched chains, such as methylcellulose)¹⁻⁷. *Leptospira*, a slender helical bacterium, swims more rapidly in such an environment than it does in water³, even at viscosities of several hundred centipoise ($1 \text{ cP} = 10^{-3} \text{ kg m}^{-1} \text{ s}^{-1}$). This behaviour is baffling until one realises that solutions of viscous agents are highly structured (gel-like). The solute forms a loose quasi-rigid network easily penetrated by particles of microscopic size. The network can exert forces

normal to a segment of the body of a slender cell even when that segment does not possess a component of velocity in the normal direction; hydrodynamic treatments of the motion of microorganisms (or of cilia and flagella) do not apply. Solutions containing highly branched polymers, for example, Ficoll, are much more homogeneous. Here, we will review existing evidence for the gel-like character of viscous agents and describe experiments in which the motion of *Leptospira* or *Escherichia coli* are compared in solutions of methylcellulose and Ficoll of the same apparent viscosity. Our data show that solutions of methylcellulose are gel-like even when quite dilute, when the bulk viscosity is as small as 2 cP.

The viscosity of a liquid, η , is defined in terms of the force, F , required to maintain a velocity gradient, dv/dx , between adjacent planes of area A ; thus, $F = \eta A dv/dx$. In a true liquid, η is independent of the size of the velocity gradient (of the rate of shear), and F is parallel to v . In a non-newtonian liquid, η depends on the rate of shear; an apparent viscosity is defined as a function of the rate of shear. If the medium is quasi-rigid, F may not be parallel to v .

A macroscopic determination of η can be made by dropping a ball through the liquid and measuring its rate of fall. The ball is subjected to a viscous force, $F = 6\pi\eta av$, where a is its radius and v its velocity (Stoke's law). η can be determined microscopically by using a sphere of microscopic size and measuring its sedimentation rate or, alternatively, its diffusion constant. The diffusion constant, D , and the frictional drag coefficient, $f = F/v$, are related by the Einstein-Smoluchowski relation, $D = kT/f$, where k is Boltzmann's constant and T is the absolute temperature. For a sphere, $D = kT/6\pi\eta a$. For water and aqueous solutions of substances of low molecular weight (MW), measurements of rates of fall, sedimentation rates and diffusion constants all lead to similar values for η , even with particles as small as globular proteins.

The situation is radically different for solutions of unbranched polymers. Their macroscopic viscosities are high, their microscopic viscosities low. A 1% solution can have an apparent viscosity thousands of times greater than that of the solvent (depending on the rate of shear and the ionic strength: the viscosity of solutions of cellulose decrease markedly at high rates of shear⁸; methylcellulose fails to increase the viscosity of 4M NaCl, K. W. Foster, personal communication). However, the sedimentation rates and diffusion constants of small particles change relatively little. Their motion depends more on the viscosity of the solvent than on the viscosity of the solution; the solution acts as a molecular sieve. For example, the diffusion constant of bovine serum albumin in 0.3% (w/v) rooster-comb hyaluronic acid (weight-average MW 1.7×10^6 , a solution of apparent viscosity about 30 times that of the solvent⁹) was found to be only 20% smaller than that in the solvent¹⁰. A similar value was observed in a 1.2% Ionagar gel¹¹. The rotational diffusion constant of serum albumin was not measurably affected by hyaluronic acid¹². In general, the larger the particle or the higher the concentration of viscous agent (or gel), the more restricted the movement^{10,11}. Methylcellulose behaves similarly¹³.

Given this porosity, it is not surprising that a bacterium that can swim in water (by whatever mechanism) can move through a solution of a viscous agent, provided that its body (protoplasmic cylinder) is sufficiently thin. Indeed, some bacteria known to swim in such solutions have been isolated on the basis of their ability to pass through cellulose ester filters (pore size 0.3 or 0.45 μm) and to form spreading subsurface colonies in 1% nutrient agar¹⁴⁻¹⁸. Other bacteria that swim in viscous media, for example, *Leptospira*, have a similar colonial morphology¹⁹. Most of these organisms are helical, but some are not^{4,18}; most are less than 0.4 μm in diameter.

When a helical bacterium swims, it spins about its helical axis. In water, more than one revolution is required to carry the cell forward a distance equal to the pitch: the helix slips circumferentially. In a solution of a viscous agent, on the other hand, the helix moves without slip, like a corkscrew through a cork. *Spirillum volutans* behaves this way in 5% gelatin²⁰. *Spirochaeta*

Fig. 1 Relative change in the rotation rates of tethered *E. coli* (strain AW405) as a function of the fluidity ($1/\eta$) of solutions of Ficoll (solid symbols, solid line) or Methocel (open symbols, dashed line). Clockwise and counterclockwise rates were normalised separately (by dividing by the corresponding rate observed in motility medium) and the mean of the two values was plotted; the two values were about the same. The mean rates observed in the absence of the polymer were 8.1 (●), 8.2 (■), 11.2 (◆), 11.4 (▲), 12.9 (▼) and 13.0 (⬢) Hz, and 6.8 (○), 6.8 (□), 7.0 (◇), 7.6 (△), 9.4 (▽), 12.6 (⋈) and 13.0 (⋈) Hz. The concentrations (% w/v) and bulk viscosities (cP) of the solutions were, respectively: for Ficoll 0, 0.802; 2.5, 1.22; 5.0, 1.76; 7.5, 2.68; 10.0, 4.61; for Methocel 0, 0.802; 0.1, 1.72; 0.2, 3.16; 0.3, 5.74. All measurements were made at 32.0 °C. The lines were drawn from the point at fluidity 1.25 through the mean values of the clusters near fluidity 0.6.

aurantia does so in 1% methylcellulose (the helical axes of the best swimmers are straight; our observation on var. *aurantia* strain J1, unpublished), so does *Leptospira interrogans* serotype *illini*²¹ (the helical axis is bent into a spiral at the front of the cell, a hook at the rear; the ends of the cell gyrate, and the protoplasmic cylinder moves without slip along the local helical axis; see also refs 7, 22-24).

This behaviour implies that solutions of viscous agents are quasi-rigid. Circumferential slip is essential if a helical object is to develop thrust in a true liquid, that is, if it is to propel itself using viscous forces; hydrodynamics demands it^{25,26}. However, it is not required in a rigid environment, that is, in one that can push on an object in a direction normal to its surface. Gray illustrated this point in a discussion of undulatory propulsion by comparing the waving motion of the tail of a spermatozoon to the serpentine movement of a snake²⁵. The resistances offered by the media through which (or over which) these organisms move (water for the spermatozoon, stones for the snake) are fundamentally different.

The helical bacteria act like passive rigid screws driven by an external torque. In *Spirillum* the torque is provided by the rotation of the polar flagella²⁰, in *Spirochaeta* by the roll (or flow) of the external sheath²⁷, and in *Leptospira* by the gyrations of the ends of the cell²¹. In a gel-like medium, the cells thread or force their way through the spaces between the molecules of solute. *Leptospira* swims efficiently in such an environment³; the gyrations of the ends of the cell are hindered, and the roll of the protoplasmic cylinder is enhanced²¹.

Leptospira behaves in a different manner in solutions of methylcellulose or Ficoll of the same apparent viscosity. It does not swim efficiently in solutions of Ficoll, which are less structured. Methylcellulose (Methocel 90 HG, 4,000 cP, Dow, a hydroxypropyl methylcellulose product) is an unbranched polymer of MW 143,000; its solutions are newtonian at concentrations of $\leq 0.5\%$ (w/v), non-newtonian at higher concentrations²⁸. A stock solution (1% w/v) was prepared in a motility medium containing 0.067 M NaCl, 0.01 M potassium phosphate (pH 7.0) and 10^{-4} M EDTA (by stirring overnight at room

temperature, 21 °C). Solutions at lower concentrations were prepared by dilution in the same medium. Ficoll (Ficoll 400, Pharmacia) is a highly branched polymer of sucrose and epichlorohydrin of MW ~400,000; its molecules are roughly spherical²⁹, its solutions newtonian³⁰. Solutions of various concentrations were prepared directly in motility medium (by stirring at room temperature). All solutions used in the experiments (of both Methocel and Ficoll) were sterilised by passage through cellulose ester filters (Millipore, pore size 0.45 µm) and stored at room temperature. Their viscosities were determined in Cannon-Ubbelohde viscometers (at the temperatures specified; flow times 1–6 min). *Leptospira interrogans* serotype *illini* was grown at 30 °C on a Tween-80 albumin medium³¹ (less glycerol) to an optical density of about 0.3 (by eye). Samples of this suspension (0.02 ml) were mixed with aliquots of solutions of Methocel or Ficoll (1 ml) and examined by dark-field microscopy (at room temperature, between a coverslip and a slide separated by a ring of Apiezon L with a Nikon S-Ke microscope: 30 W tungsten or 100 W tungsten-halogen lamp, ultra dark-field condenser, Fl 40× plan objective, 15× oculars).

Serotype *illini* translated rapidly in 1% Methocel ($\eta = 95$ cP at 32 °C, our measurements; 140 cP at 25 °C and zero rate of shear, ref. 28). It swam in a serpentine fashion in the hook-spiral configuration, spiral-end first, the protoplasmic cylinder moving without slip^{21–24}. Cells with only one hook (or spiral) translated at about the same speed, spiral-end first or hook-end last²¹. Translational velocities of more than $20 \mu\text{m s}^{-1}$ have been reported for other strains in similar media³. In contrast, serotype *illini* failed to translate in 35% Ficoll (92 cP at 21 °C). The ends of the cell gyrated slowly; the body remained nearly stationary. The cells had a tendency to wind up on one another.

Differences between the motion of serotype *illini* in solutions of Methocel or Ficoll were still marked at concentrations at which both media are thought to be newtonian^{28,30}. The cells translated well in 0.25% Methocel (4.3 cP at 32 °C) but not as well as in 1% Methocel. Some slip of the protoplasmic cylinder was apparent. Cells with only one hook (or spiral) moved more rapidly spiral-end first than hook-end last. In contrast, the motion in 10% Ficoll (4.6 cP at 32 °C) was hard to distinguish from that in motility medium. The cells gyrated and rolled rapidly but translated slowly. Cells with only one hook (or spiral) moved spiral-end first but not hook-end last²¹.

A more quantitative idea of the difference in behaviour between solutions of Methocel and Ficoll was obtained by comparing the rotation rates of tethered *E. coli* in the two media. Cells were grown and tethered as described previously³² and observed at 32 °C, either with the tracking microscope³³ or with a version of the linear-graded filter apparatus³⁴ in which an image from the microscope is analysed directly. The same cell was studied in Ficoll or Methocel at various concentrations. With Ficoll the rotation rates were nearly inversely proportional to the viscosity, as expected if the flagellar motors run at a constant torque; with Methocel they were not (Fig. 1). Solutions of Methocel perturbed the motion of *E. coli* less than did solutions of Ficoll of the same apparent viscosity; evidently, the cells were able to push the chains of methylcellulose out of the way and to move more as they would in pure solvent. Note that all the solutions used in these experiments were passed through Millipore filters (see above); they were homogeneous both by eye and by phase-contrast microscopy. However, differences were apparent to *E. coli*, even at the smallest concentrations tested (Ficoll 2.5% w/v, Methocel 0.1% w/v).

Many kinds of bacteria swim more rapidly in dilute solutions of viscous agents (viscosities of the order of 2 cP) than they do in ordinary media^{1,2,6}. The efficiency of flagellar propulsion is probably enhanced by the gel-like structure of these solutions. Dextran, a branched polysaccharide, failed to show the effect¹; Ficoll has not been tested. Flagellar bundles are more easily seen in solutions of viscous agents than in ordinary media^{35–38}. Is this also due to a qualitative change in the structure of the medium? Does Ficoll show this effect? Is there a better agent that could be used for experiments of this kind? The choice is limited, as most

bacteria fail to swim in solutions of high ionic strength or high osmolarity. If one's purpose is to slow the motion of a micro-organism (or a cilium or flagellum) while keeping the hydrodynamics the same, Ficoll is a better choice than methylcellulose or probably any other unbranched polymer.

We thank E. Canale-Parola and N. W. Charon for cultures. This work was supported by grants from the US NSF.

Growth of human B-lymphocyte colonies *in vitro*

RECENTLY developed *in vitro* culture systems that support clonal formation of lymphoid cells have promoted remarkable advances in our understanding of lymphocyte proliferation and the nature of the proliferating cells. Human T lymphocytes from venous blood, bone marrow and lymphoid organs and murine T and B lymphocytes from lymphoid tissues have been grown into colonies of T and B cells in semisolid culture. In these systems, T-lymphocyte colony formation requires that the seeded cells undergo T-mitogen stimulation, that is, by phytohaemagglutinin (PHA) or concanavalin A, and B-lymphocyte colony growth necessitates sensitisation by mercaptoethanol, a humoral thymic factor, or a polyclonal B-cell activator, such as lipopolysaccharide, purified protein derivative or dextran sulphate^{1–7,17}. Previous attempts to achieve colony formation of human B cells were unsuccessful, even in the presence of known polyclonal B-cell activators. However, in certain experimental conditions, the plant lectins, pokeweed mitogen (PWM) and PHA, stimulate both human B and T lymphocytes into transformation and

Fig. 1 Viewed under a light microscope at low magnification, unstained colonies grown in agar medium from human, venous blood, B-lymphocyte-enriched population stimulated with PHA. *a*, Large colonies (type I) containing 250–500 cells which developed within the upper agar layer 5 days after seeding; *b*, small, flat colonies (type II) of 50–100 cells which grew on the surface of the upper agar layer 7 days after plating.

proliferation in cell culture with a synergistic effect between the sensitised T and B cells^{8–13}. We report here that, based on this information and earlier techniques for clonal formation of human lymphocytes *in vitro*, we have evolved a two-layer soft agar culture technique in which the mitogens, PHA and PWM, were able to generate the appropriate signal for triggering B-lymphocyte precursors of venous and umbilical cord blood, tonsil, adenoid and chronic lymphatic leukaemia (CLL) origin into colony-forming and immunoglobulin-producing cells.

Lymphoid cells, obtained from human adenoids and tonsils excised in sterile conditions, were suspended in Dulbecco's modified Eagle's medium (MEM). The cells were incubated for 20 min at 37 °C in MEM containing 50 µg ml⁻¹ erythromycin and 200 µg ml⁻¹ kanamycin, then washed twice and resuspended in MEM. Heparinised blood (10 IU ml⁻¹) was obtained from umbilical cord, healthy adult donors and patients in whom

CLL had been diagnosed but who had not received therapeutic treatment. Lymphocytes were isolated by Lymphoprep (sodium metrizoate/Ficoll) gradient (D 1.077)¹⁴, washed twice with MEM containing penicillin and streptomycin (100 U ml⁻¹ and 100 µg ml⁻¹, respectively) and resuspended at 10⁶ cells per ml of the same medium supplemented with 12.5% of inactivated pooled human serum.

B-lymphocyte-enriched populations were obtained from mononuclear cells by separating E-rosette-forming cells by density sedimentation through Lymphoprep. The T-cell-depleted interphase fraction contained at least 70% B cells when normal blood was processed, 65% B cells for cord blood, 70% for tonsils and 80% for CLL. B cells were quantitated by direct immunofluorescent staining of surface membrane immunoglobulins (SmIg) with fluorescein isothiocyanate-conjugated anti-µ chain or polyvalent rabbit antiserum to human immunoglobulins¹⁵. The B-cell-enriched population contained <4% E-rosette-forming cells. For sensitising the cells with mitogen in liquid phase, suspensions of B-cell-enriched populations or mononuclear cells (10⁶ cells per ml MEM containing 12.5% human serum) were incubated with PHA-M (Difco, 0.0125 ml ml⁻¹) or PWM (Sigma 2.5 µg ml⁻¹) for 72 h at 37 °C in a water-saturated atmosphere of 7.5–9% CO₂ in air (Table 1). The sensitised cells were then washed, resuspended and seeded in the upper soft agar layer (0.32% agar), at 5 × 10⁵ cells per

Fig. 3 Colony cells from PWM-stimulated, cord blood B-cell-enriched population, 6 days after plating, stained with May-Grünwald Giemsa. All cells had the morphological features of transformed lymphoblastoid and small or large plasmoid cells.

Fig. 2 Lymphocyte colony number and their cell SmIg, grown in Bacto agar from mitogen-stimulated lymphoid cells. All B-cell-enriched populations and CLL cells (80% B lymphocytes) developed into B-cell colonies with a characteristically high content of SmIg⁺ colony cells. Colonies grown from unfractionated lymphocytes from normal human venous blood were uniformly SmIg⁻ and those stemming from normal human lymphoid tissue had few SmIg⁺ cells. The data represent the average of 3 or more experiments (2–4 plates per culture). *a*, B-cell-enriched population; *b*, mononuclear cells.

30-mm Petri dish. The lower agar layer (0.5% agar) contained either 0.0125 ml PHA per ml medium or 2.5 µg PWM per ml medium. The Petri dishes were incubated at 37 °C in a fully humidified atmosphere at 7.5–9% CO₂ in air. In some experiments cell-free lymphocyte culture fluid (LCF) obtained from a 3-day culture of cord blood lymphocytes (1.5 × 10⁶ cells per ml MEM containing PHA 0.0125 ml ml⁻¹ or PWM 2.5 µg ml⁻¹) replaced the MEM of the lower agar layer¹⁶. For controls we used cultures which did not contain mitogen in the lower agar layer or in which the lymphocytes seeded in the upper layer had not been presensitised with mitogen.

The formation of the colonies and their morphology were observed under an inverted microscope. Colonies of 50 or more cells developed from PHA-stimulated cells 3–5 days after seeding and from PWM-treated cells after 5–7 days. Seeded PWM-sensitised, B-cell-enriched populations proliferated and formed lymphocyte colonies only when the soft agar culture had been supplemented with LCF. Two types of colonies formed: type I, large colonies containing 50–500 cells appeared within the upper layer, and type II, small, flat colonies containing 50–150 cells developed above the primary colonies, on the surface of the upper agar layer (Fig. 1). A stationary period of 2–3 days (PHA) or 4–5 days (PWM) followed colony development; the colonies began to degenerate on days 7–9, with cell disintegration and lysis. As distinct from the large primary colonies, the number of flat colonies varied greatly. We decided to use the score of the large primary colonies as a parameter for evaluating the effect of stimulation and growth conditions on lymphoid cells. When cord blood cells were seeded, a new kind of colony, composed of small macrophages, formed 12–13 days after culture.

To characterise the nature of the colony cells, 4–6-day colonies were collected, and their cells pooled and washed.

Table 1 Surface markers on mononuclear cells and B-cell-enriched populations before and after mitogen sensitisation

Source of cells	Cell population	% E rosettes	Liquid phase		
			0 h % SmIg ⁺	72 h, PHA* % SmLg ⁺	72 h, PWM* % SmIg ⁺
Peripheral blood	B cell	3.3±0.6	71.7±0.9	73.3±6.6	71.7±0.9
	Mononuclear	75.0±4.1	10.7±0.4	10.7±4.1	12.0±4.2
Cord blood	B cell	3.7±1.1	65.0±4.1	73.0±8.7	77.3±6.2
	Mononuclear	45.0±4.1	11.3±1.3	11.0±2.9	15.3±1.1
Adenoids	B cell	4.0±0.5	71.5±1.5	59.0±9.0	66.0±1.0
	Mononuclear	60.0±0.5	32.5±2.5	21.0±1.0	24.0±0.0
Tonsil	B cell	3.5±0.2	75.0±3.0	68.0±4.0	67.0±3.0
	Mononuclear	39.0±1.0	50.0±0.0	22.5±10.5	25.0±5.0
Peripheral blood (CLL)	Mononuclear	9.7±5.3	79.7±1.3	86.0±2.9	

'B cell' refers to the B-lymphocyte-enriched population, 'Mononuclear' to unfractionated mononuclear cells. It was found that in mitogen-sensitised lymphocyte populations, spontaneous E-rosette formation was no longer specific for T cells.

*After 72 h stimulation with mitogen, the cells were plated in the two-layer soft agar system.

After agar residues had been removed by passing the cell suspension several times through a tuberculin syringe and needle, SmIg were assayed. Detection of SmIg was used as the membrane marker for characterising colony cells. B-cell-enriched populations gave rise to B-cell colonies, as manifested by the large number of colony cells having SmIg⁺, and mononuclear cells evolved T-cell colonies, with SmIg⁺ colony cells (Fig. 2). Also, B-lymphocyte colony growth was consistently obtained from blood and lymphoid tissue B-cell-enriched populations sensitised with PHA or PWM and from CLL (80% B cells) treated with PHA. Mononuclear cells from normal peripheral blood gave rise to colonies whose cells bore no SmIg; among those from cord blood or lymphoid tissue, where the ratio of B to T cells is high, 1–4% SmIg⁺ cells were seen.

Morphological examination of the large B-cell colonies that developed from PHA-induced cells showed that these had compact centres whereas those that grew from PWM-treated cells had a loose, diffuse structure. From a microscopic study of colony cells, we found that both type I and type II colonies contained many ellipsoid or spherically shaped, large mononuclear cells with a blast-like appearance, that is, a round nucleus and basophilic cytoplasm, and plasmoid cells having the

characteristic eccentric nucleus and bulky basophilic cytoplasm (Fig. 3). In CLL colonies, many cells resembling small or medium-sized lymphocytes were also seen. The progeny cells generated by PWM-stimulated B lymphocytes were more differentiated than those of the PHA-treated cells. Electron microscope studies of the cells in B colonies that developed from PHA- and PWM-stimulated populations showed that these had the morphological features of either blast-like or plasmoid cells. Many strands of well developed rough-surfaced endoplasmic reticulum with cisternal dilations were observed, particularly in the PWM-treated cells (Fig. 4).

Differences in the number and morphology of PHA- and PWM-induced colonies and their component cells, dissimilar colony development times and distinct culture conditions (the need for lymphocyte culture fluid for colony formation of PWM-induced cells) indicate that the two mitogens may act either on different B-cell subpopulations or on a B-cell population at different stages of maturation.

This technique for cloning B cells from normal and leukaemic B lymphocytes in soft agar conditions should be a major breakthrough in investigations concerned with the mechanism of the immune response of normal and leukaemic lymphoid populations. It should be particularly helpful for analysing functional B-cell populations, and the role of monocytes and T cells in the activation of B lymphocytes and regulation of their colony growth.

This study was supported in part by a research grant from the Chief Scientists, Israel Ministry of Health. We thank Ms H. Deshen for her editorial assistance.

Fig. 4 Electron micrograph of a cell from a colony developed from PHA-sensitized normal venous blood, B-cell-enriched population 4 days after plating. Note that the eccentric nucleus (N) contains increased euchromatin. In the cytoplasm there are large and short rough-surfaced endoplasmic reticulum profiles (ER), many polyribosomes, a centriole (C), the Golgi apparatus (G) and different-sized mitochondria (M). ($\times 7,000$.)

Cooperation between antigen-reactive T cells and anti-idiotypic B cells in the anti-idiotypic response to antigen-antibody complexes

THE variable regions of antibody molecules carry unique antigenic determinants (idiotypes), which have been shown to be isoimmunogenic, that is, immunogenic in syngeneic animals¹⁻³. Jerne and others^{4,5} have proposed that autoimmune responses to self-idiotypes might form the basis of an immunoregulatory network, and evidence in favour of this hypothesis has been reported from several laboratories⁶⁻⁸. Preformed antigen-antibody complexes of dinitrophenylated keyhole limpet haemocyanin (DNP-KLH) and the DNP-binding myeloma protein M315 are very effective in inducing iso-anti-idiotypic antibodies to the M315 idiotypic in BALB/c mice⁹, and formation of immune complexes during an antibody response could therefore represent the mechanism whereby self-idiotypes become autoimmunogenic. As such anti-idiotypic antibody responses are T-cell-dependent, one must assume that if animals are immunised with purified antibody then anti-idiotypic T (helper) cells cooperate with anti-idiotypic B cells. The existence of iso-anti-idiotypic T cells has been formally demonstrated^{10,11}. When an antibody is administered as an immune complex, a similar cooperative event may occur; but it is also possible that antigen-specific T cells cooperate with idiotypic-specific B cells through the immune complex, as the latter can prime animals for immunity to the antigen¹² and to idiotypic determinants on the antibody (see below). Here I present evidence that this occurs.

Table 1 Cooperation between KLH-primed spleen cells and anti-M315 B cells

Group*	B cells primed with†:	KLH-primed spleen cells‡	Boost §	IBC ($\mu\text{g ml}^{-1}$)¶
1	DNP-BSA-M315	+	DNP-KLH-M315	43.0 ± 11
2	DNP-BSA-M315	+	M315	0.4 ± 0.2
3	DNP-BSA-M315	-	DNP-KLH-M315	2.4 ± 1.0
4	Nothing	+	DNP-KLH-M315	1.7 ± 0.5

*Irradiated (500 R) BALB/c mice ($n = 4$).

†Spleen cells from BALB/c mice given 10 μg (wt of DNP₅₀BSA) DNP₅₀BSA-M315 (1:10 w/w ratio) complexes 3 weeks previously. These cells were treated with anti-Thy 1 antiserum and rabbit complement (45 min for 37°C) and each mouse received 20×10^6 viable cells.

‡ 20×10^6 spleen cells from mice given 100 μg alum-precipitated KLH plus 2×10^9 *Bordetella pertussis* organisms 1 month previously.

§10 μg DNP-KLH-M315 complexes (1:5 w/w ratio) or 50 μg M315 given intravenously.

¶Idiotypic-binding-capacity (determined by double antibody radioimmunoassay using ¹²⁵I-labelled M315 (refs 9, 16) of sera taken 10 d post-transfer.

The first indication for this mechanism emerged from an experiment where mice were immunised with DNP-KLH-M315 immune precipitates, as described previously⁹. Three weeks later, some were boosted with M315 and others with complexes. Those boosted with M315 had similar anti-M315 antibody titres on day 31 to unboosted mice, whereas those boosted with DNP-KLH-M315 gave a true secondary response (data not shown).

In the experiment shown in Fig. 1 BALB/c mice were given DNP-KLH-M315 complexes at w/w ratios of antigen:antibody of 1:10 (antibody excess) or 1:1 (antigen excess)⁹, with or without alum-precipitated carrier, that is, KLH. Administration of KLH increased anti-M315 antibody titres, but only after boosting with immune complexes. The effect was most marked after an optimal (10 μg DNP-KLH) priming dose of DNP-KLH-M315 (1:10) complexes (fourfold increase in antibody),

and less with a 1- μg dose of complexes. Complexes prepared at a 1:1 ratio elicit poor anti-M315 antibody titres, and KLH priming did not enhance their immunogenicity. Priming with KLH also enhanced the anti-DNP antibody response in those mice given 10 μg DNP-KLH-M315 (1:10) (data not shown). Complexes in antigen excess and in antibody excess both induced anti-DNP antibodies (not shown), but only those in antibody excess induced substantial anti-M315 antibody titres.

The helper effect of KLH priming could have been due to the induction of KLH-specific T-helper cells, or to the enhanced production of anti-KLH (or anti-DNP) antibodies¹³. In subsequent experiments groups of mice were immunised with 1:10 complexes of DNP-bovine serum albumin (DNP-BSA) and M315. Three weeks later B cells from these mice were transferred with spleen cells from KLH-immunised mice (as a source of T-helper cells) to irradiated recipients, which were boosted with either DNP-KLH-M315 or M315 (Table 1). Mice given DNP-BSA-M315-primed B cells plus KLH-primed cells gave a marked anti-M315 response, but only when boosted with DNP-KLH-M315, and not when boosted with M315. DNP-BSA-M315-primed B cells alone gave a very weak response, comparable to that given by unprimed B cells plus KLH-primed cells.

In a further experiment irradiated mice were given B cells from mice primed with purified M315 in adjuvant³, with or without purified KLH-primed T cells (Table 2). Again, those given helper cells produced substantial anti-M315 antibody titres, but only when boosted with DNP-KLH-M315 complexes. The idiotype specificity of the cooperation is indicated by the low antibody titres of the group boosted with DNP-KLH-M460 complexes. M460 is a DNP-binding IgA myeloma protein with a different idiotypic from M315. The binding of the antibodies in group 1 to M315 was almost completely inhibited by 10^{-3}M DNP-lysine (not shown), indicating that they were primarily directed against the combining site of the antibody.

These experiments therefore suggest that in mice immunised with antigen-antibody complexes, antigen-specific helper cells can cooperate with anti-idiotypic B cells to generate an anti-idiotypic antibody response. Indeed, the available data suggest that this form of cooperation is the most important in anti-idiotypic immunity to immune complexes. It is unlikely that KLH priming induces anti-idiotypic T cells, since mice do not respond to purified M315 when given KLH-primed T cells and M315-primed B cells (Tables 1, 2). In addition, T cells from mice

Fig. 1 Effects of carrier (KLH) priming on the anti-idiotypic response to DNP-KLH-M315 complexes. Groups ($n = 4$) of BALB/c mice were given 10 or 1 μg (wt of DNP-KLH) DNP₁₇₂KLH-M315 complexes (w/w antigen: antibody ratios 1:10 or 1:1 (ref. 9) intravenously on day 0. Some also received 100 μg alum-precipitated KLH intraperitoneally on the same day. The mice were bled on day 21 (■), boosted with 10 μg DNP-KLH-M315 and finally bled again on day 32 (□). Anti-M315 antibody titres were determined by double-antibody radioimmunoassay^{9,16}.

IBC, idiotype-binding capacity.

Table 2 Cooperation between KLH-primed T cells and anti-M315 B cells

given bovine gamma globulin do not provide help in this system, thus confirming the antigen specificity of the helper effect (Table 2).

The results shown in Fig. 1 suggest that in the conditions used here DNP-KLH-M315 complexes do not prime KLH-specific T-helper cells optimally (see also ref. 12). Perhaps antigen-antibody complexes do not prime anti-idiotypic T-helper cells efficiently either, or alternatively they may induce anti-idiotypic suppressor cells. The co-existence of anti-DNP and anti-idiotypic antibodies in mice immunised with DNP-KLH-M315 complexes suggests that the M315 idiotype is not a prominent component of the anti-DNP antibody repertoire of the BALB/c mouse. As there is evidence that these mice do make the M315 idiotype in response to DNP¹⁴, another possibility is that administration of M315 complexes suppresses the expansion of the B-cell clone making this idiotype.

In the context of network theories of immunoregulation⁴, the present results suggest that if the generation of immune complexes during an antibody response represents the physiological mechanism for inducing autoimmunity to idiotypes, then these complexes need only prime anti-idiotypic B cells to give an anti-antibody response. These cells could then cooperate with pre-existing antigen-specific T-helper cells, thereby bypassing the requirement for anti-idiotypic T-helper cells.

Micropuncture of lateral intercellular spaces of *Necturus* gallbladder to determine space fluid K^+ concentration

EPITHELIA such as that of *Necturus* gallbladder consist of a pavement-like sheet of uniform cuboidal cells of $20 \times 20 \times 20 \mu\text{m}$. As seen in the electron microscope, the clefts between the cells (lateral intercellular spaces, LIS) are ~ 0.1 – $1 \mu\text{m}$ wide. They are closed against the gallbladder lumen by so-called 'tight' junctions—which, however, allow the passage of small ions¹—and at the other end communicate more freely with the interstitial fluid compartment of the body through slits of > 30 – 50 nm width. The lateral membranes of the epithelial cells which face the LIS are highly folded (the surface amplification factor in *Necturus* gallbladder is around 20 (ref. 2) but the basal membranes which face the interstitial fluid compartment directly are not, and so it is evident that virtually all matter which is reabsorbed from the lumen after passing the cell membranes (or the tight junctions) must enter the LIS before it reaches the interstitial fluid compartment proper. It is generally assumed that the LIS have a central role in isotonically transporting epithelia by acting as the main coupling site between salt and water transport. Although elaborate models have been used in attempts to describe the salt and water coupling in detail mathematically^{3–9}, the results have been inconclusive, mainly because there was no definitive experimental proof. A central question, whether or not the LIS fluid is hypertonic as postulated by the standing gradient hypothesis of isotonic fluid absorption³, remained open, until recently, when the first direct measurements of the ion concentrations in the lateral spaces were published¹⁰. These data were obtained by means of electron-probe analysis of frozen tissue sections of rabbit ileum and revealed a substantial hypertonicity. We have tried the alternative approach of measuring the ion concentrations in the LIS directly using ion-selective microelectrodes. Our observations, which are reported here, indicate that as far as the K^+ concentration is concerned the ion accumulation in the LIS of *Necturus* gallbladder is much lower than suggested by the electron-probe data from rabbit ileum.

We chose an *in vitro* preparation of *Necturus* gallbladder¹¹ in which we can recognise the LIS under $\times 640$ magnification with

Table 1 Results from measurements with double-barrelled K^+ -selective electrodes

Potential (mV)	f (%)	c_K (mmol l^{-1})	Localisation	Depth of tip penetration
+0.4	71	3.4	Colour	
–1.9	89	4.6	Colour	
–0.9	97	3.2	Colour	
+1	100	3.0	Colour	
+1.5	100	2.8	Profile	
–0.5	96	4.9	Mark	50–75%
+0.2	95	4.4	Mark	50–75%
–2	77	4.6	Mark	~50%
-0.28 ± 1.28		3.9 ± 0.8		

'Potential' is the LIS potential referred to subepithelial space. f is the fraction of the overall transepithelial resistance which was observed in the LIS; low values of f indicate the presence of some leak between gallbladder lumen and LIS along the electrode path. c_K is the K^+ concentration of LIS fluid. It was measured by filling one electrode barrel with Corning no. 477317 potassium exchanger as described previously¹² and the other barrel with Ringer solution, recording the potential difference between both barrels and reading c_K from a calibration curve¹². 'Localisation' gives the means of localisation. Because bevelling of double-barrelled electrodes resulted in tip diameters of 1.2 – $2 \mu\text{m}$, the last experiments were carried out with unbevelled tips of $< 0.5 \mu\text{m}$ diameter, which did not allow colour ejection. Hence, localisation was achieved by recording the potential profile and the advance of a dye mark on the electrode.

Fig. 1 Photomicrographs of fluid ejection into lateral intercellular spaces. The electrodes were filled with Ringer's solution containing in mmol l^{-1} : NaCl, 110; KCl, 2.5; CaCl_2 , 1; NaHCO_3 , 10, to which 1% of Kiton blue was added. After bevelling of the tip to 0.8–1.2 μm o.d. or, respectively, 70–95 $\text{M}\Omega$ resistance, enough colour could be ejected to give a clear indication of the position of the electrode tip. *a*, Electrode and epithelium before puncture; *b*, after puncture and during fluid ejection at slightly shifted focus. Between the arrows, the colour can be seen to fill a LIS, although the contrast in the black and white reproduction is poor. *c*, A similar picture of another LIS; *d*, the same place after cessation of fluid ejection and after the electrode has been moved slightly laterally.

a water immersion lens. The bladder was mounted between two half-chambers and bathed on either side with Ringer's solution. We first tried to define criteria for successful impalements of the LIS and measured the electrical parameters of the LIS. Glass micropipette electrodes were mounted on a Leitz micro-manipulator and manually advanced from the lumen compartment into a cell and then further in the direction of a LIS. Because the electrode tip is not visible inside the tissue and because the tissue is usually slightly squeezed by the advancing electrode, we verified the location of the electrode tip by ejecting coloured electrode fluid. Essentially four different images could be distinguished microscopically. (1) Injection into a cell. This led to sharply outlined, homogeneous and persistent staining of a single cell. (2) Injection into subcellular cystic spaces. This yielded a sharply defined, small, persistent coloured dot, which tended to grow slightly with time of ejection but never reached the size of a cell. Communication with the gallbladder lumen along the electrode shaft was frequently observed. (3) Injection into a LIS. Depending on the shape of the LIS this resulted in a more or less sharp outline of the space between two cells (Fig. 1), with occasional additional coloration of neighbouring spaces and faint coloration of the immediately underlying subepithelial space. In contrast to cell staining, the coloration of the LIS never persisted, disappearing within approximately 10 s of cessation of ejection from the electrode tip. (4) Injection into the subepithelial space. This resulted in diffuse coloration of a larger subepithelial area with a quite sharply defined front at the basal end of the epithelium but otherwise uncertain delineation. No backflux into the spaces

from underneath was observed. Depending on the amount of colour ejected, the subepithelial space cleared again in less than 1 min.

Although image (1) was correlated with the recording of a cell potential, the potential always dropped towards zero when the tip had entered a LIS (image (3)). In 10 measurements on 8 bladders a stable (> 1 min) potential difference of -1.61 (s.d. ± 0.96) mV (range -2.5 to $+0.8$) was recorded, LIS negative with respect to mucosal compartment. Referred to the serosal potential, which was measured immediately after each successful puncture by advancing the electrode further into the subepithelial space (image (4)), the potential of the LIS was 0.03 ± 0.83 mV negative which is not different from zero. (The transepithelial potential difference averaged 1.58 mV, lumen positive in these experiments.) We also continuously recorded the voltage divider ratio by passing square-wave constant current pulses of up to 100 μA , 1 s width and 0.1 Hz repetition rate across the bladder, and recording the potential deflections in the cell, the LIS and the subepithelial compartment. Expressing the data as fractional resistances (f) it was found that, on its way from the mucosal compartment into the LIS, the electrode tip had passed on average $97.8 \pm 4.7\%$ (range 90–104%) of the resistance between mucosal compartment and subepithelial space, indicating that the electrical resistance from LIS into the serosal fluid compartment was negligible. Image (2) was usually connected with a near-zero potential reading, but the simultaneously recorded fractional resistance was much lower than 100%.

In further experiments, we used double-barrelled micro-electrodes, with one barrel acting as K^+ -sensitive electrode and the other as reference. Because the localisation by fluid ejection was not always possible we determined the position of the electrode tip in some experiments from the potential and resistance profile and from the position of a lacquer mark which had been placed at a known distance of $\sim 40 \mu\text{m}$ from the tip. Thus, we assumed, in agreement with the above observations, that the tip had entered a LIS when, on advancing the electrode, the cell potential collapsed but f remained high, and when subsequent further advancement yielded a new cell potential (when the slightly diagonally moving electrode had crossed the LIS and penetrated the adjacent cell). The latter criterion as well as the depth of insertion, as read from the dye mark, distinguished LIS from subepithelial measurements.

Table 1 gives the results from eight stable measurements in six bladders. They yield a mean K^+ concentration for the LIS fluid of $3.9 \pm 0.8 \text{ mmol l}^{-1}$, which is significantly higher than the K^+ concentration of the mucosal and serosal bathing solution. To test the validity of our measuring technique we also determined the K^+ concentration in the subepithelial space by advancing the electrode from a LIS across the neighbouring cell into the underlying connective tissue. These measurements yield a mean K^+ concentration of $2.4 \pm 0.6 \text{ mmol l}^{-1}$ ($n = 9$) which is similar to that of the Ringer's solution. Although our measurements are not sufficiently advanced to yield complete concentration profiles along the LIS for all ions of interest (attempts to measure the Na^+ concentrations have been unsuccessful because of technical problems with the electrodes) we think that they open a new experimental approach towards a better understanding of the function of the LIS. Our observation that the K^+ concentration of the LIS is only slightly higher than that of the external bathing solutions calls for some caution with respect to the interpretation of concentration profiles from electron-probe data. Even though the latter data¹⁰, which show K^+ concentrations of up to 40 mmol l^{-1} , were obtained on a different tissue of a different species and at higher ambient K^+ concentrations (15 compared with 2.5 mmol l^{-1}), they are difficult to reconcile with the present findings, because there is no reason to believe that part of the space fluid K^+ should be bound (assuming that the sampling area of the electron beam does not include lateral folds² of the cell membranes).

We thank Mrs B. Gebler and the technical staff of the Max-Planck-Institute for assistance.

Deficient production of tyramine and octopamine in cases of depression

THE cause or causes of depressive illness are unknown, although biochemical evidence points to a physical basis for the psychiatric and somatic features of the disease¹. For nearly 20 years, the amine hypothesis² has been the most favoured explanation and putative derangements of noradrenaline and/or 5-hydroxytryptamine economy have been invoked as the systems of primary disturbance. Careful scrutiny, however, has revealed major inconsistencies in this hypothesis³. Some of the strongest evidence in its favour has been the ability of tricyclic antidepressant drugs to act as potent monoamine uptake inhibitors, thus potentially facilitating neurotransmission at the synaptic cleft; but recently, two drugs in this group, iprindole and mianserin, have been shown to be devoid of both noradrenaline and 5-hydroxytryptamine re-uptake-inhibiting ability, although each is a clinically effective antidepressant (for review see ref. 4). Two things should be pointed out in this connection. First, most pharmacological experiments performed to test the hypothesis have focused on noradrenaline and 5-hydroxytryptamine, whilst a possible role for the so-called trace amines⁵ has been almost completely neglected. And second, the direct clinical approach based on the detection of possible metabolic abnormalities has resulted in conflicting and controversial data³. We now report preliminary evidence pointing to a deficient production of two trace amines, tyramine and octopamine, in patients with depressive illness.

Thirteen females (mean age, 56.9 ± 3.2 yr) and 10 males (mean age, 57.6 ± 2.8 yr) suffering from primary depressive illness⁶ were studied. They had no history of mania or of significant physical illness. On admission, all were withdrawn from antidepressant or neuroleptic medication and placed on

placebo tablets for 7–10 days. In certain cases, night-time sedation (nitrazepam, 10 mg) was allowed for a few days. At the end of this 'drug-free' washout period, the patients were assessed for the severity of their disease by the Hamilton rating scale (HRS)⁷ for depression. The assessment on HRS was made by two independent raters who showed a satisfactory concordance ($r = 0.98$; $P < 0.001$). Only patients scoring 16 or more on the first 16 items of the HRS were included in the study. All were assessed on the Newcastle diagnosis scale⁸ and were assigned a diagnostic score placing them along an endogenous–non-endogenous dimension.

The control subjects were drawn from laboratory and hospital staff and were not on any form of medication. They included 17 females (mean age, 48.5 ± 2.2 yr) and 10 males (mean age, 52.9 ± 2.7 yr). Whilst no attempt was made to give patients or controls a standardised diet, patients received a full hospital diet during their drug-free period and controls living in hospital received a diet almost identical to that of the patients.

Mean 24-h urinary excretion values for free phenolic acids, total phenylacetic acid and free phenylethylamine in patients and controls are shown in Tables 1 and 2. Controls living in hospital had a similar excretion pattern of amine metabolites to those living outside hospital. The mean output of both *p*-hydroxyphenylacetic acid and *p*-hydroxymandelic acid (the major metabolites of *p*-tyramine and *p*-octopamine⁹) in depressed patients was significantly lower than that of controls (Table 1). When males and females were compared separately, the difference was also evident but only reached significance in females. There was no correlation with age. These results were examined in relationship to the patients' Newcastle scale scores. The three with high scores (9–11) on this scale, characterised by severe endogenous features and responding poorly to tricyclic drugs¹⁰, had very low excretion values of *p*-hydroxymandelic acid (4.64 ± 0.29 μmol per 24-h) and *p*-hydroxyphenylacetic acid (53.8 ± 13.0 μmol per 24-h) although the other metabolites were normal. The only other significant finding was that male depressives excreted more 4-hydroxy-3-methoxymandelic acid than females. These findings suggest that the deficit was a selective one and did not derive from some technical source of error such as incomplete sample collection.

The trace amines⁵ are represented in the brain in nanogram concentrations only. However, high tissue concentrations of catecholamines and 5-hydroxytryptamine stem not so much from increased production but from the existence of large storage depots. In addition, their assay is relatively simple whereas suitable quantitative procedures for the trace amines and their metabolites have become available only relatively recently⁵. It is important to note that the absence of a specific storage mechanism does not necessarily imply that turnover is any less rapid than that of compounds possessing one. Daily whole-body octopamine production, for example, falls little short of that of the individual catecholamines¹¹.

Free phenylethylamine was determined by an electron-capture gas chromatographic method¹⁸. Values are means $\pm$ s.e.m.

first time appear to support this view, it must be remembered that an unknown proportion of these acidic metabolites may derive from diet or gut flora (for extended discussion, see ref. 9). *p*-Hydroxyphenylacetic acid and *p*-hydroxymandelic acid, which presumably reflect quantitatively the turnover of their precursor amines, are metabolically interconnected (Table 1). Even though changes in phenylethylamine production are likely to have been masked by a massive gut flora contribution⁹, our recent findings of significantly low concentrations of phenylacetic acid, the major metabolite of this amine, in cerebrospinal fluid from patients with depressive illness¹² suggests that phenylethylamine too may be deficient in the central nervous system of these patients.

Note also that an as yet unknown proportion of the total production of both tyramine and octopamine derives from the periphery, particularly the sympathetic nervous system and the tissues it innervates¹³. However, even if the changes we have described were to prove to be wholly peripheral, and such a finding need not necessarily detract from their relevance to depression, this disease may well turn out to stem from a generalised upset, connected perhaps with a membrane transport deficit, rather than a disturbance localised solely to the brain¹⁴.

What lessons are we to draw from the present findings? We have no wish to substitute a tyramine-octopamine hypothesis for its competitors. Recent data implicating histamine H₂ receptors in the therapeutic response to tricyclic antidepressant drugs⁴ are particularly compelling but by no means exclude other factors. It seems that an extremely complex sequence of events is responsible for the maintenance of normal affect, in which histamine, catecholamines, 5-hydroxytryptamine, and the trace amines also, may all play their part. Recent trials have indicated that when administered orally, phenylalanine, the precursor of phenylethylamine, tyramine and octopamine, may be beneficial in certain patients with depressive illness¹⁵.

Sulphonation of cholinergic receptor disulphide bond increases response to ACh

THE presence on the cholinergic receptor of a critical disulphide bond has been demonstrated and localised to within 10 Å of the cholinergic receptor anionic binding subsite¹⁻⁴. Reduction of this bond by dithiothreitol results in a reduced response of the nicotinic cholinergic receptor to acetylcholine (ACh) in many systems^{1,5-8}. I report here that heterolytic cleavage of this disulphide bond is produced using sodium bisulphite, a reagent which shows a high degree of specificity, reactivity and reversibility of interaction with the disulphide bond⁹. The active agent is the bisulphite ion, the reaction being

and resulting in the addition of the strongly nucleophilic sulphonate group to the receptor. The addition of this group seems to modify the ACh receptor-ionophore complex in a unique manner which results in an increase in its response to ACh.

The preparation used was the cutaneous pectoris muscle of the frog *Rana pipiens*. Reagents were added to continuously perfusing frog Ringer (NaCl 115 mM, KCl 2.0 mM, CaCl₂ 0.2 mM, MgCl₂ 5.0 mM, buffered with HEPES, pH 7.2, at room temperature). Sodium bisulphite was effective in concentrations of 10⁻⁵-10⁻³ M. All compounds were bath applied with the exception of the ACh iontophoretic experiments. The amplitude of either the miniature end plate potential (m.e.p.p.) or iontophoretically-induced ACh responses were used as a measure of the postsynaptic response to ACh.

The application of 1 mM NaHSO₃ to the preparation results in an increase in m.e.p.p. amplitude within 5 min, most typically with a 1-min latency. This increase may be up to 300%, although increases of 50-100% are more common. The amplitude increase is not the result of a single class of large m.e.p.ps but rather a shifting of the entire amplitude spectrum to the right (Fig. 1a, b). Iontophoretic application of ACh shows this amplitude increase to be of postsynaptic origin (Fig. 1c). The rise or delay time of the response to ACh (m.e.p.p. or iontophoresis) and the input impedance of the postsynaptic membrane (measured with two intracellular electrodes) are unchanged by bisulphite. The resting potential of the postsynaptic membrane remains constant even after a 2-h application of bisulphite in concentrations up to 5 × 10⁻³ M. (Presynaptic effects of bisulphite, including m.e.p.p. frequency increases shown in Fig. 1a, will be reported elsewhere.)

From the above data, it can be concluded that the increased response to ACh following bisulphite application cannot be attributed to changes in the postsynaptic membrane input resistance (no change in input impedance), to an action on acetylcholinesterase (no change in response decay time) or to changes in presynaptic release (response to iontophoretic ACh increases). An action on the postsynaptic cholinergic receptor molecule thus seems a possibility. As the bisulphite ion has a high degree of specificity of reaction with disulphide bonds⁹ and as a disulphide bond on the cholinergic receptor has been shown to be critical in postsynaptic ACh action¹⁻⁴, the following experiments were carried out using compounds known to

Fig. 1 Increases in response to ACh following sodium bisulphite. *a*, Intracellularly recorded m.e.p.ps before and 15 min after NaHSO₃ application (10^{-3} M); *b*, m.e.p.p. amplitude spectrum of the same muscle fibre during control recording and 15 min after NaHSO₃ treatment (10^{-3} M); *c*, response of postsynaptic membrane to iontophoresed ACh (large arrows) before and after NaHSO₃ application (10^{-3} M). Small arrows indicate m.e.p.ps.

localise the site of action of a reagent to this disulphide bond of the cholinergic receptor^{1-4,8}.

DTNB [5,5'-dithiobis(2-nitrobenzoic acid)] forms an addition product with sulphhydryl groups which then revert to the oxidised state of the disulphide bond⁹. It will reverse the reduction of the disulphide bond on the cholinergic receptor produced by dithiothreitol¹. The effect of DTNB on the bisulphite-induced amplitude increase was thus tested. Application of DTNB (0.2×10^{-3} M) after bisulphite treatment (10^{-3} M) produces a rapid return of the m.e.p.p. amplitude to control values (Fig. 2). DTNB, without prior bisulphite treatment, has no effect on the end plate at this concentration. The accelerated reversal of the bisulphite response by DTNB most probably occurs by combination of DTNB with free -SH groups and -SH groups produced by hydrolysis of the easily reversible sulphonate⁹.

MBTA [4(*N*-maleimido)- α -benzyltrimethylammonium-iodide] was synthesised as an affinity label for sulphhydryl groups located near the cholinergic binding site². MBTA alkylates covalently at its maleimide group and binds reversibly at the quaternary end of the molecule to the cholinergic ligand binding site. Through the irreversible alkylation, MBTA prevents restoration of the disulphide bond by DTNB and at the same time keeps its quaternary group in the vicinity of the cholinergic binding site where it competes with ACh for the receptor site². Application of MBTA (5×10^{-7} M) following application of bisulphite, reduces the postsynaptic response to ACh, presumably by competitive inhibition of the quaternary group of MBTA with the spontaneously released ACh. It also prevents the DTNB reversal of the bisulphite response to control values (Fig. 3). MBTA without prior bisulphite treatment has no effect either pre- or postsynaptically at this concentration.

Occupation of the receptor binding site by ACh has been shown to prevent the reaction of dithiothreitol with the receptor disulphide bond⁸. The experiment was repeated using sodium bisulphite and ACh to ascertain whether the binding of ACh to the receptor would also prevent the action of the bisulphite ion on the receptor. Following a control m.e.p.p. recording, the muscle was exposed for 2 min to ACh (5×10^{-6} M) and then for 20–40 min to ACh (5×10^{-6} M) plus sodium bisulphite (3×10^{-3} M). This concentration of bisulphite would invariably have produced a high m.e.p.p. frequency and large amplitude increase. However, during application and the subsequent 40 min Ringer wash, no change in m.e.p.p. amplitude and only a small change in m.e.p.p. frequency occurred. The contralateral muscle used as a control showed the usual bisulphite effect. These experiments were also repeated with fibre sampling: 20 fibres were sampled, at each experimental point above, with the same results. Occupation of the receptor by ACh seems to inhibit disulphide bond modification either by preventing access to the bond by steric hindrance or by induction of a conformational change after which the disulphide bond is either inaccessible or no longer essential for further receptor-ionophore interaction. Evidence that steric hindrance is not the mechanism of ACh protection is given by the fact that curare, a bulky molecule which binds to the cholinergic receptor, is

Fig. 2 DTNB reversal of m.e.p.p. amplitude and frequency increase following NaHSO₃ application (10^{-3} M). DTNB (0.2×10^{-3} M) was applied 40 min after NaHSO₃ application, when m.e.p.p. frequency and amplitude were maximal. Reversal begins approximately 2 min post-DTNB and is complete at 20–40 min.

Fig. 3 Use of alkylating affinity label MBTA to demonstrate the presence of the sulphhydryl group produced by NaHSO_3 application. MBTA (5×10^{-7} M) is applied after bisulphite has produced a m.e.p.p. amplitude increase. The production of a sulphhydryl group by bisulphite is shown by the presence of affinity alkylation as demonstrated by (1) failure of DTNB to produce reversal of the MBTA response and (2) reduced m.e.p.p. amplitude produced by competition of spontaneously released ACh with the quaternary group of the affinity label.

unable to block the action of dithiothreitol⁸. Desensitisation of the ACh receptor does not seem to be involved in the process of ACh protection, as it has been shown that receptors in the desensitised state are still accessible for reduction by dithiothreitol⁸.

The above data demonstrate an action of bisulphite on the postsynaptic cholinergic receptor which increases the receptor response to ACh. Bisulphite is known to produce a heterolytic cleavage of disulphide bonds with resultant addition of a sulphonate group⁹. This action has been localised to a disulphide bond in the vicinity of the receptor negative subsite by the use of MBTA and is likely to be the same disulphide bond which has been reduced by dithiothreitol in previous experiments¹⁻⁸. The mechanism of action of this increased response to ACh following sulphonation remains unclear, but must be linked to the addition to the receptor molecule of the negative charge of the sulphonate group.

This work was supported by a GRS grant from Rutgers Medical School, CMDNJ. I thank Stephen Highstein and Paul Stein for equipment loans, and Arthur Karlin for the supply of MBTA. Part of the research was conducted at the Marine Biological Laboratory, Woods Hole.

A semi-synthetic penicillinase inactivator

MANY pathogenic bacteria secrete penicillinases (β -lactamases, EC 3.5.2.6) as a defence mechanism against β -lactam antibiotics¹. Inhibitors of penicillinase are therefore of potential clinical importance, and interest in this area has been stimulated by the discovery of effective naturally occurring enzyme inactivators²⁻⁴. We have studied the interaction of one of these, clavulanic acid (I) with the exocellular enzyme from *Staphylococcus aureus*, and we report here the synthesis of a novel penicillinase inhibitor whose design was based on the mechanism postulated for the inactivation by clavulanate.

Sodium clavulanate rapidly inactivates the penicillinase from *S. aureus* with close to 1:1 stoichiometry. Partially inactivated enzyme regains 10-15% activity over 10 min at pH 7 and 25 °C; fully inactive enzyme can be prepared by treatment with a small excess of inactivator. The apparent K_m for inactivation is 12 μM , and the enzyme is protected from inactivation by good substrates such as the chromogenic cephalosporin, 87/312 (ref. 5), or by competitive inhibitors such as phenylacetylcephalosporin C. Clavulanate is therefore a highly specific active site-directed inhibitor of *S. aureus* penicillinase.

Fig. 1 Difference spectra, (enzyme + clavulanate) - enzyme, for an equimolar mixture of enzyme and inhibitor, 3.5×10^{-5} M, at pH 8 and 25 °C. *a*, Is the baseline, *b*, the spectrum immediately after mixing. The successive spectra with isosbestic point 292 nm were taken 1, 3, 6, 10, 20 and 35 min after mixing.

Incubation of the protein with clavulanate leads to the appearance of a new component in the UV spectrum, whose evolution is shown in Fig. 1. Loss of activity is associated with the rapid appearance of a species with maximum absorbance at wavelength (λ) 290 nm. In a slower process, not accompanied by any change in the extent of inactivation, this species is converted into another, with $\lambda_{\text{max}} = 278$ nm and extinction coefficient $21,500 \text{ cm}^{-1} \text{ M}^{-1}$. Inhibited enzyme can be fully reactivated by incubation in acid solution. Figure 2 shows that this restoration of activity is paralleled by loss of absorbance due to the UV chromophore. The kinetics of the reactivation were measured between pH 5 and 10.5. In this range the rapid phase of the reaction is first order, with the rate constant decreasing from 0.12 min^{-1} at pH 5 to $<0.001 \text{ min}^{-1}$ at pH 10.5. The slow phase leading to complete reactivation shows a similar pH dependence. Hydroxylamine has no effect on the reaction.

The simplest hypothesis to explain these results is that inhibition is due to formation of a compound of partial structure II from the β -lactam ring of clavulanate. 'A' represents an enzyme

active site residue. We suggest that this structure is an analogue of an acyl enzyme in the normal reaction pathway, stabilised to hydrolysis by the unsaturation at C5-C6 (ref. 6). A compound containing this structure (ethyl β -benzylaminocrotonate) has $\lambda_{\max}$ 286.5 and 275.5 nm, and extinction coefficients 23,400 and 28,800 $\text{M}^{-1} \text{cm}^{-1}$ in the *cis* and *trans* forms, respectively (in 95% ethanol)⁷, and these values are typical of β -amino- α , β -unsaturated carbonyl compounds⁸. We suggest therefore that the slow change in spectrum (Fig. 2) is due to *cis-trans* isomerisation. Structures of type II are expected to be unstable in acid because of tautomeric equilibria with imines (III), whose hydrolysis is acid catalysed. A model compound, ethyl 3-carboxymethylamino-2-butenate, synthesised by condensation of ethylacetoacetate and glycine, showed the expected spectrum and acid instability.

If this proposal for the mechanism of inactivation is correct, the difference that makes clavulanate an inactivator of the enzyme and closely similar compounds, such as the penicillins (IV) substrates, is the possibility of an elimination across the C6-C5 bond. This elimination could occur by a two-step route

or, as proposed by Charnas *et al.*⁹, by single-step abstraction of a proton from C6 by an enzymatic base. It is not possible to decide between these routes on the basis of present evidence. Either way, elimination requires a sufficiently good leaving group at C5, and a proton which can be lost from C6.

Fig. 2 Correlation of restoration of activity with loss of UV absorbance. Penicillinase (2.7×10^{-5} M) in 0.1 M sodium acetate buffer, pH 5.0, was incubated at room temperature with an equal concentration of clavulanate. The absorbance at 278 nm and the enzymatic activity were measured at intervals over the next 3.5 h.

Oxygenation of sulphur makes it a better leaving group¹⁰, and we therefore synthesised penicillin G sulphone¹¹. This compound was found to be a good substrate, with K_m 20 μM and $V_{\max}$ the same as for penicillin G. The sulphone does not inactivate the enzyme, but a transiently formed (non-enzyme-containing) hydrolysis product has $\lambda_{\max}$ 280 nm. Presumably, in this case the elimination only occurs after the penicilloic acid has left the active site.

Penicillins lack one of the two hydrogen atoms at C6 in clavulanate and elimination by the single-step route may be sterically impossible in penicillins and derivatives. Alternatively, the hydrogen atom in penicillin G sulphone may be too weakly acidic. 6-Chloropenicillanic acid, as usually synthesised¹² (but see also ref. 13), has the opposite configuration at C6 to that in penicillins, and such an electronegative substituent presumably has an acid-strengthening effect on the hydrogen atom. We therefore synthesised 6- α -chloropenicillanic acid, and found it to be a poor substrate for the enzyme ($K_m = 3\text{--}5$ mM, $V_{\max}$ 0.8 relative to penicillin G = 100). The compound is not an inactivator of the enzyme. Oxidation of 6- α -chloropenicillanic acid with KMnO_4 gave the novel 6- α -chloropenicillanic acid sulphone (V).

Incubation of the enzyme with this compound leads to inactivation similar to that produced by clavulanate, except that (1) no reactivation of the enzyme is observed at pH 7, and (2) the enzyme hydrolyses about 100 molecules of the compound for each molecule of the enzyme that is inactivated. This behaviour is thus similar to that found for the reaction of clavulanate with the *Escherichia coli* enzyme^{9,14}. The apparent K_m for the inactivation process is about 100 μM . We anticipate that the stability of the inactivated form of the enzyme will allow identification of the site of attachment of the inhibitor.

English *et al.* have reported¹⁵ that unsubstituted penicillanic acid sulphone inhibits penicillinases, including that from a strain of *S. aureus*. It seems likely that the mechanism of this inhibition is similar to that proposed here.

We thank Martin Cole of Beecham for the clavulanate and Glaxo Research for the 87/312. S.J.C. is the holder of an SRC Research Studentship.

In vivo proteolytic cleavage of colicins requires specific receptor binding

COLICINS are plasmid-specified antibiotic proteins produced by some strains of coliform bacteria¹. They are distinguished from other bacterial antibiotics such as aminoglycosides and tetracyclines by their large molecular weights (40–80,000) and their narrow host range. Colicins only kill bacteria having the appropriate cell-surface receptors^{1,2}, and even then the ability of a cell to produce a given colicin usually confers immunity to killing by that colicin. We are interested in the comparative properties of colicins and their similarities to bacterial toxins that are active against mammalian cells, some of which are also encoded by extra-chromosomal elements. A fundamental question concerning the action of both colicins and toxins is how these large, essentially hydrophilic proteins traverse the mainly hydrophobic cell surface to reach the lesion sites. For colicins these include DNA for colicin E2 (ref. 3), RNA (colicin E3 and cloacin DF13)^{4,5}, and presumably the inner cell membrane, where membrane potential and energy metabolism are affected (colicins E1, K and Ia (refs 2, 6, 7)). Here, we show that binding of colicin to its specific receptor can result in a specific proteolytic cleavage to generate two peptide fragments. The smaller of these, derived from the C-terminal region of the colicin, has a greater specific biological killing activity *in vitro* than the parent molecule. We propose that *in vivo* the proteolytically derived

Fig. 1 For analytical purposes, 0.17 nmol purified colicins¹⁰ were incubated with 0.1 A₆₀₀ units of *Escherichia coli* K12 outer membranes¹² in 0.1 M sodium phosphate buffer (pH 7.0) for 15 min at 37 °C. Membranes were removed by centrifugation (78,000g, 90 min) and the peptides resolved by Laemmli SDS (0.1%) polyacrylamide slab gel electrophoresis¹³ (4.5% stacking gel, 12.5% running gel). Co-run MW markers were used in the determination of the MWs of the colicin polypeptides. For preparative gels, 13.3 nmol of digested colicin was run in wide tracks on each gel. Each colicin sample was flanked by a track containing MW markers. The latter tracks only were stained and by reference to the analytical results, each band containing a presumptive colicin-derived polypeptide was cut out, disrupted in distilled water (18 h, 4 °C) and finally dialysed extensively against distilled water. 90% of the product (about 50 nmol) was lyophilised, and then used in determination of N- and C-terminal residues and N-terminal sequences^{17–19}. The remaining sample was precipitated by (NH₄)₂SO₄ (70% w/v) and dialysed against the appropriate reaction buffer before assaying for *in vitro* activities. Intact colicins were treated in the same way before structural determination and *in vitro* assay. C-terminal peptides = OM_C; N-terminal peptides = OM_N. For example, E1-OM_C = C-terminal colicin E1 polypeptide derived from incubation of colicin E1 with outer membranes.

Fig. 2 Colicin E3(a) or E3-OM_C(b) were incubated with ribosomes from sensitive K12 cells²⁰ using the polyacrylamide gel assay method of Lau and Richards⁴. The amount of the nucleotide fragment generated from 16S rRNA was quantified using a Joyce-Loebel densitometer. 80–500 pmol E1-OM_C, K-OM_C and E2-OM_C, colicins E1, E2 and K and all OM_N fragments (Fig. 1) gave no measurable generation of nucleotide fragment (similar traces to the bottom one in a).

C-terminal fragment is transported across the cell surface to the lesion site. This process seems analogous to the apparent cleavage of diphtheria toxin during its entry into mammalian cells⁶.

Because colicins E2 and E3, and cloacin DF13 can be cleaved by pure proteases to yield specific polypeptide fragments, some of which have the nuclease activity of their parent colicin *in vitro* but not *in vivo*^{4,9–11} it seemed possible that colicins, after binding to their specific receptors on whole cells, might be proteolytically cleaved to generate a biologically active fragment which is then transported to the lesion site. To test this for colicins E2, E3, E1 and K, we incubated purified colicins separately with outer membrane vesicles¹², derived either from colicin-sensitive cells (receptor intact) or from resistant cells (receptor non-functional). Incubation of each colicin with colicin-sensitive outer membrane vesicles resulted in a complete conversion of each colicin to two peptides, derived from each end of the colicin molecule (Fig. 1). In contrast, vesicles from an E-colicin-resistant, K-colicin-sensitive (E^r K^s) strain cleaved colicin K but not E, whereas vesicles from an E^s K^r strain cleaved E but not K colicins. None of the colicins were cleaved by outer or inner membranes from E^r K^r strains or by inner membrane vesicles from sensitive cells. Lysozyme, ovalbumin, cytochrome *c* and bovine serum albumin were not cleaved during incubation with any of the vesicles.

Although none of the fragments isolated from preparative SDS-polyacrylamide gels¹³ killed whole cells, even after extensive dialysis, the C-terminal peptides derived from colicins E2 and E3 showed activity in *in vitro* assays. Moreover, their specific activities were higher than those of their parent colicins isolated in the same way. The specific activity of the colicin E3 C-terminal fragment was 300–1,000 times greater than that of the intact colicin (Fig. 2). Colicin E2 DNase specific activity was about 1% of that of its C-terminal peptide (Fig. 3).

In an attempt to assay the *in vitro* activities of colicins E1 and K and their polypeptide fragments, we used the enhanced fluorescence assay of Phillips and Cramer¹⁴. Incubation of colicin E1 (Fig. 4a) or colicin K (Fig. 4b) with intact sensitive cells in

the presence of 8-anilino-1-naphthalene sulphonic acid (ANS) resulted in a large rapid increase in fluorescence, whereas incubation with colicin-resistant cells showed no fluorescence increase. The much smaller increase in fluorescence observed when intact colicins E1 and K were incubated with outer membranes of $E^s K^s$ cells could reflect the binding of colicins to their receptors on the outer membrane. Incubation of C-terminal colicin E1 (E1-OM_c) and C-terminal colicin K (K-OM_c) peptides with inner membranes resulted in a slow but reproducible increase in fluorescence. This may reflect a significant interaction of these polypeptides with their presumptive lesion site in the inner membrane, as N-terminal colicin E1 and K peptides (E1-OM_n, K-OM_n), and colicins E2 and E3 and their peptides had no such effect. If these interactions with inner membranes are of significance, then E1-OM_c and K-OM_c are more active than their respective whole colicins.

Fig. 3 DNase activity of colicin E2 and its polypeptide fragments. Colicins or their peptides (Fig. 1) were incubated with 0.6 μ g bacteriophage λ DNA for 1 h at 37°C in 16 μ l of the reaction mixture of Schaller and Nomura³. Samples were then assayed on a 0.9% agarose gel⁵. The direction of DNA migration is indicated. Much of the undigested λ has remained at the origin of the gel. We have noted this with many DNA preparations, and it could result from the binding of DNA to non-DNA macromolecules present as contaminants in the DNA preparation. The amount of protein ($\text{mol} \times 10^{-15}$) added for each assay is indicated above each track, and the degree of digestion is indicated below. Colicins E1, K, E3, their peptides and E2-OM_n (not shown), and bacteriophage λ incubated in the absence of added protein, showed no detectable digestion.

Although *in vitro* target activity is associated with the C-terminal fragments, all N-terminal peptides bound cell-surface receptors (Fig. 5). Furthermore, additions of N-terminal fragment in a 10^4 – 10^5 -fold molar excess to homologous colicin inhibited killing activity. Predictably, K-OM_n did not interfere with E-colicin killing and N-terminal colicin E fragments did not affect K-colicin killing. None of the C-terminal fragments effected *in vivo* killing by any colicin.

In conclusion, these data demonstrate that after cell-receptor binding, colicins can be proteolytically cleaved into two peptides with mutually exclusive receptor binding and killing activities. This seems analogous to the proposed action of diphtheria toxin on mammalian cells⁸. Common factors include protein fragmentation into large (molecular weights 38,000 and 35–36,000)

Fig. 4 Fluorescence changes (502 nm) after colicins and their polypeptide fragments (71 pmol per assay; Fig. 1) were added (0 min) to 8 A_{600} units of the indicated cell preparation in 1 ml of M9 salts, equilibrated with ANS (60 μ M). *a*, Colicin E1-derived polypeptides; *b*, colicin K-derived polypeptides. $\circ$, Intact colicin + $E^s K^s$ cells; Δ , intact colicin + inverted spheroplasts²¹ of $E^s K^s$ cells; ∇ , intact colicin + inner membranes¹² of $E^s K^s$ cells; $\square$, intact colicin + outer membranes¹² of $E^s K^s$ cells; $\blacktriangle$, -OM_c peptides + inverted spheroplasts of $E^s K^s$ cells. $\blacktriangledown$, -OM_c peptides + inner membranes of $E^s K^s$ cells. The following combinations of colicin-derived peptides (71 pmol) and cell preparations gave <2% fluorescence change at any time during the 60-min incubation (values within the parallel arrows) (1) Any cell preparation incubated with E1-OM_n; K-OM_n; colicin E2, E3 or any of their fragments. (2) Whole $E^s K^s$ cells or their outer membranes incubated with E1-OM_c and K-OM_c. (3) $E^s K^s$ cells and their outer membranes incubated with intact colicins.

cell binding and small (24,000 and 19–21,000) *in vitro* killing fragments, neither fragment having *in vivo* activity. However, although the action of diphtheria toxin requires cleavage of disulphide bonds, none are present in E and K colicins (D.H.W., unpublished). Another common feature between colicins, diphtheria toxin and some other bacterial toxins is that they are encoded by extra-chromosomal elements: this may have facilitated their spread among bacteria and their evolution¹⁵. Specific cell-surface-associated proteolysis is clearly a key step in the action of some bacterial toxins or bacterial and mammalian cells: whether this same protease is responsible for the cleavage and release of secreted proteins¹⁶ remains to be seen.

Fig. 5 Five nmol ^{14} C-labelled colicin or proteolytic fragments^{22,23} (see Fig. 1: 65.3–161.2 $\times 10^3$ c.p.m. per 5 nmol) were incubated with sensitive (upper bar) or $E^s K^s$ cells (lower bar, shaded) (10^8 cells ml^{-1}) for 30 min in 1 ml L-broth. After centrifugation and resuspension (boiling 1% SDS), the cell pellet was counted on 1 MM Whatman paper using 0.15% diphenyloxazole in toluene.

Induction of erythroid differentiation in the human leukaemia cell line K562

MURINE erythroleukaemic cell lines can be induced by various low molecular weight compounds to differentiate *in vitro*¹. Corresponding human cell lines have not previously been described but we now report that human leukaemic cells of the K562 cell line can be induced to red cell differentiation *in vitro*.

Table 1 Accumulation of erythrocyte-like, benzidine-positive particles in sodium butyrate treated cultures

Days in culture	Per cent of benzidine positive particles*				
	0	1	2	3	4
1 mM Na-butyrate	1.4	3.9	12	35	48
Control	1.4	0.9	0.9	1.1	1.4

*Cyto-centrifuged smears were stained with benzidine-Giemsa. Percentages were calculated by counting more than 300 cells.

The K562 line was originally established by Lozzio and Lozzio from the pleural effusion of a patient with chronic myelogenous leukaemia in terminal blast crisis². This cell line, which has been considered to represent an early differentiation stage of the granulocyte lineage³, is commonly used as a sensitive target cell in the human natural killer cell assay⁴.

We have recently analysed the surface glycoprotein patterns of various established human haematopoietic cell lines^{5,6} and those of isolated populations of normal and leukaemic leukocytes⁷⁻⁹. The surface glycoprotein pattern of K562 cells was found to be clearly different from those of benign and malignant cells representing various stages of the myeloblast to granulocyte differentiation sequence. In contrast, we observed several common features of normal erythrocytes and K562 cells. These observations led us to investigate more closely the K562 cells.

The cells were cultivated in RPMI 1640 culture medium supplemented with 10% newborn-calf serum. K562 cells carry on their surface¹⁰ and synthesise¹¹ glycophorin A, which is the major sialoglycoprotein on human red cells¹². This provides additional evidence for the erythroid nature of the K562 cells, as glycophorin A is known to be expressed exclusively on basophilic normoblasts and on later stages of the red cell differentiation in human bone marrow¹³. The K562 cells evidently also contain spectrin as seen by indirect immunofluorescence using rabbit anti-spectrin antibodies on acetone-fixed smears (data not shown).

Fig. 1 Microphotographs of cyto-centrifuged smears of K562 cells cultivated for 4 days in the presence of 1 mM sodium butyrate. *a*, Stained with Giemsa-eosin and photographed using a green filter. *b*, Stained with Lephene's benzidine method-Giemsa and photographed using a red filter. *c-e*, Details of the apparent sequence of generation of erythrocyte-like particles in butyrate induced K562 cultures. The arrow indicates a normoblast-like cell. These were stained with Giemsa-eosin and photographed with a green filter.

Fig. 2 *a*, Cell counts from K562 cultures treated with 1 mM sodium butyrate (●) and from control cultures without inducer (○). Each point represents the average from duplicate determinations. *b*, Synthesis of haemoglobin in sodium butyrate induced K562 cells as determined by radioimmunoassay. K562 cells were cultivated at an initial density of 0.2×10^6 cells per ml in the presence of 1 mM sodium butyrate (●) or without inducer (○) (the same cultures as in *a*) and aliquots taken on indicated days. After washing the cells three times in phosphate-buffered saline, aliquots were removed for protein determination¹⁵. The rest of the samples were solubilised in Triton X-100 containing buffer and used for radioimmunoassay. Anti-haemoglobin antiserum was prepared in rabbits and anti-rabbit IgG in sheep. Haemoglobin was radioiodinated with ¹²⁵I by the chloramine T method¹⁶. The antibody concentration was calibrated to bind approximately 30% of the radioactivity and more than 95% of the binding was inhibited by nonradioactive haemoglobin. The preparation of antisera and the radioimmunoassay will be described in detail elsewhere. The results are given as μg haemoglobin per g of protein and each point represents the average of duplicate analyses.

As the cultures of K562 cells were found to contain occasional benzidine-positive particles (Table 1) the differentiation capacity of this cell line was further investigated. Because the commonly used inducing agent dimethyl sulphoxide¹ did not cause obvious erythroid differentiation, sodium butyrate was used as inducer¹⁴. When K562 cells were cultivated for 4 days in the presence of 1 mM sodium butyrate (optimal concentration 1–3 mM) differentiation was observed. This amount of sodium butyrate did not significantly affect the growth rate of the K562 cells (Fig. 2*a*). Eosinophilic particles resembling erythrocytes accumulated in the cultures. These particles were surrounded by a membrane and showed positive staining reaction with benzidine (Table 1) indicating the presence of haemoglobin (Fig. 1). The induction of haemoglobin synthesis was confirmed by radioimmunoassay (Fig. 2*b*).

The mode of generation of the erythrocyte-like particles seems to be unusual. Although occasional normoblast-like cells were seen (Fig. 1*e*), most of the erythrocyte-like particles are apparently generated intracytoplasmically (Fig. 1*c*). As shown in Fig. 1*c–e* this seems to start with an accumulation of cytoplasmic eosinophilic inclusions which condense to one or several erythrocyte-like particles which are subsequently expelled. Scanning electron microscopy shows the erythrocyte-like particles to be spherical with a smooth surface resembling spherocytes (in preparation). The mechanism may be similar to the platelet generation by megakaryocytes. The phenomenon of *in vitro* erythrocyte generation by this cell line is being further studied using time-lapse cinematography.

The findings presented here not only prove the erythroid character of the K562 cell line, but also further emphasise that malignant transformation of human haematopoietic cells does not necessarily mean irreversible loss of differentiation capacity. After 8 years in culture *in vitro*, the K562 cell line has retained its ability to react to appropriate stimuli by undergoing erythroid differentiation. The effect of sodium butyrate on human erythroid leukaemic cells might have interesting clinical implications.

This study was supported by the Academy of Finland and by the Finnish Cancer Society. We thank Liisa Alajoki and Anneli Asikainen for technical assistance. K562 cell lines were obtained from Dr G. Klein (Karolinska Institute, Stockholm) and Dr K. Nilsson (Uppsala).

Cleavage site of bacteriophage fd gene II-protein in the origin of viral strand replication

DOUBLE-STRAND DNA replication of small single-stranded bacteriophages such as ΦX174 and filamentous phage fd is initiated by highly specific endonucleases. This was demonstrated *in vitro* with the isolation of $\Phi\text{X cisA}$ protein¹ and more recently with that of fd gene II-protein². Both endonucleases produce one single-strand break in the viral strand of superhelical RFI providing an origin for double-strand (ds) DNA replication^{3,4}. For gene II-protein the strand specificity of nicking was demonstrated by cleavage of asymmetrically labelled fd RFI (viral strand ³²P-labelled, complementary strand ³H-labelled) and subsequent alkaline sucrose sedimentation. As a result the viral strand was cleaved into a full length linear form, whereas the complementary strand remained circular (T.F.M. and K.G., submitted). Here we report the position of the nick in the nucleotide sequence of the fd genome.

Gene II-protein was purified from *Escherichia coli* cells infected with phage fd mutants in gene V using the stimulation of DNA synthesis on fd RFI as an assay. The purification steps were ammonium sulphate precipitation and various columns. Details of the isolation procedure will be published elsewhere (T.F.M. and K.G., submitted). The pure enzyme has a molecular weight of 46,000 on SDS gels and under non-denaturing conditions which agrees with the size of gene II-protein from membranous cells structures. The protein was not found in cells infected with phage mutants in gene II.

Superhelical fd RFI DNA was incubated with purified gene II-protein as described in the legend to Fig. 1 resulting in the open circular form (RFII₀). (Phage fd RFII₀ is defined as the cleavage product of fd RFI by gene II-protein.) To determine the exact position of the nick RFII₀ was cleaved with restriction

Fig. 1 Localisation of the gene II-protein cleavage site on the fd genome by gel electrophoresis of labelled DNA fragments. The cleavage reaction was carried out with 0.5 pmol (2 μ g) fd RFI and 0.3 units of purified fd gene II-protein (T.F.M. and K.G., submitted) in 150 μ l 10% sorbitol, 20 mM Tris-HCl, pH 8.1, 80 mM NaCl, 5 mM β -mercaptoethanol, 5 mM MgCl₂ and 200 μ g bovine serum albumin per ml for 10 min at 30 °C. The reaction product was then digested with restriction endonucleases *Hind*II (tracks a, b), *Bam*HI (c, d), or *Hae*III (e, f). The DNA was denatured in the presence of 5 μ g fd single-stranded DNA in 0.2 M NaOH for 20 min at 37 °C. The sample was mixed with 200 μ l phenol and 50 μ l 1 M KH₂PO₄, the aqueous phase desalted on a Sephadex G50 column and lyophilised. Tracks b, d and f are controls without gene II-protein. Labelling at the 3'-end (a-d) was done with nucleotidyl transferase (EC 2.7.7.31) (5 units) in 1 mM CoCl₂, 5 mM MgCl₂, 50 mM imidazol-HCl, pH 6.8 and 1.2 μ M [α -³²P]dTTP (2 $\times$ 10⁶ c.p.m. in the 25 μ l assay) for 30 min at 37 °C. The reaction products were analysed on a 5% acrylamide gel. Label at the 5'-ends (e, f) was introduced by T4-polynucleotide kinase (EC 2.7.1.78) after pretreatment with alkaline phosphatase (EC 3.1.3.1) and the fragments separated under denaturing conditions on a 10% polyacrylamide gel¹⁰. The numbers in the figure give the nucleotide length of the fragments generated and the letters the separated *Hae*III fragments, which were also a marker for the tracks a and b. Tracks g and h show a 20% sequencing gel¹⁰ covering the 3' terminus of the 54 nucleotide fragment H'. Strong and weak Py bands correspond to C and T residues, respectively. The very strong bands on top are non-degraded 54 nucleotide fragment.

endonucleases (Fig. 1). The generated fragments were denatured in alkali terminally labelled and analysed by electrophoresis on acrylamide gels. When RFII₀ was cleaved with endonuclease *Hind*II, an additional fragment of about 650 nucleotides was found, when cut by enzyme *Bam*HI, a fragment of about 130 nucleotides appeared in comparison with the control experiment using RFI DNA (Fig. 1). These results indicate that the gene II-protein cleavage site maps around position 5,750 between the *Bam*HI site at nucleotides 5,645/5,646 and the *Hind*II site at nucleotide 6,408/1 within the intergenic region of the phage (Fig. 2). For a more precise analysis restriction enzyme *Hae*III was used. Gel analysis of the denatured reaction products showed two new fragments of 54 and 49 nucleotides derived from the 103 nucleotide *Hae*III fragment (Fig. 1). Nucleotide sequences at the 3'-end of the two fragments (Fig. 1) and comparison with the known fd nucleotide sequence⁵ revealed the position of the gene II-protein cleavage site in the viral strand between nucleotide 5,781 and 5,782 (Fig. 3). As gene II-protein is a component of fd RF replication with purified proteins⁴, it seems likely that the enzyme creates a start for DNA synthesis. This origin of phage fd viral strand synthesis lies within the segment derived *in vivo* for the start of DNA replication in the related phage f1 (ref. 6).

Cleavage of fd RFI by gene II-protein gives a 5'-phosphate end and a 3'-OH end. The viral strand at the nick can be extended in the 3' direction with nucleotidyl transferase (small fragment in Fig. 1, track c). The 5'-end can be labelled with polynucleotide kinase only after phosphatase treatment (fragment of 49 nucleotides in Fig. 1, track e). Labelling was as efficient as at the *Hae*III created 5'-end of the adjacent fragment H'. Thus, gene II-protein is not covalently bound to the DNA ends at the nick after alkaline treatment, but it may well be attached to the 5'-end in native conditions. A covalent linkage was postulated for Φ X174 *cisA* protein at the 5'-end of the cleaved viral strand, as label could not be introduced at this end⁷.

The position of the nick between nucleotides 5,781 and 5,782 has several consequences for phage DNA replication and recombination (see Fig. 3). (1) The cleavage site is separated from the origin of complementary strand synthesis⁸ by 24 nucleotides. The complementary strand can therefore only be initiated on the displaced viral strand after a full round of viral strand synthesis. (2) The nick lies in a nucleotide sequence with

Fig. 2 Physical and genetic map of the bacteriophage fd genome. The inner segments represent the genes and the intergenic region (IG) of the phage. The outer segments give the fragments produced by restriction endonuclease *Hae*III. The arrows at the outside indicate the cleavage sites of restriction endonucleases *Hind*II and *Bam*HI, and of gene II-protein, respectively. The arrows in the IG region indicate start and direction of viral strand (v) and complementary strand (c) synthesis. Counterclockwise movement on the map corresponds to the 5' $\rightarrow$ 3' direction of the viral strand DNA. The numbers at the outside indicate the nucleotide position on the genome.

Fig. 3 Nucleotide sequence of the origins of phage fd replication. The interrupted arrows indicate sequences of twofold symmetry around the cleavage site of gene II-protein, which may be in equilibrium with a hairpin in single-stranded viral DNA and in superhelical RF DNA. Viral and complementary strand synthesis start closely neighboured but without overlap. In the larger phage fd 75 (H. F. Lauppe and U. Hess, unpublished) a tandem duplication of base pairs reaches from the gene II-protein cleavage site into gene IV (ref. 9).

twofold symmetries (Fig. 3). As gene II-protein neither reacts with fd single strands nor with relaxed doubly closed fd RF (T.F.M. and K.G., submitted), we assume that transient hairpin structures in the locally disturbed DNA double helix are recognised by the enzyme. The self-annealing structure may also be required for circularisation of linear single strands in RF and viral strand synthesis. (3) The nick in the RF also represents a hot spot for recombination with homologous sequences in other parts of the genome which result in duplications of DNA segments found in variants of filamentous bacteriophages⁹.

Premature termination during adenovirus transcription

INITIATION of transcription, the first event in gene expression, is probably the most critical possible site for gene regulation. However, it has become clear from recent studies with bacteria and bacteriophages that a transcriptional start does not ensure the expression of a gene. For example, the phenomenon of 'attenuation', that is, premature termination of an mRNA chain before transcription of the structural gene region, is a key regulatory event for the synthesis of enzymes that make amino acids in bacteria¹⁻⁴. We report here evidence for premature chain termination during transcription of an animal virus genome.

Late in adenovirus type 2 (Ad2) infection of HeLa cells a large group of virus-specific mRNAs⁵⁻⁷ are produced by processing

Fig. 1 Sedimentation analysis of 'nascent' Ad2-specific nuclear RNA. *a, b*, Labelled nuclear RNA was extracted from Ad2-infected HeLa cells after a 45-s label with ³H-uridine. $1-2 \times 10^8$ cells were collected 16-18 h after infection, resuspended at 4×10^6 cells ml⁻¹ with 1 mCi ³H-uridine ml⁻¹, final concentration 0.05 μ mol uridine ml⁻¹; after 45 s the cells were poured over frozen crushed medium. The extracted RNA was treated with dimethyl sulphoxide at 65 °C as described previously^{8,17} and sedimented at 25 °C in sucrose SDS gradients. Markers were either A₂₆₀ furnished by ribosomal RNA or ³²P-labelled ribosomal RNAs. The positions of 45S and 18S are indicated. Fractions of the gradients equivalent to 10^7 cells were hybridised²⁷ to 2 γ of Ad2 DNA adsorbed to nitrocellulose filters (●). RNA:DNA hybridisation was carried out as described at 65 °C in 2 $\times$ TES buffer containing 0.3 M NaCl, 0.01 M TES, 0.01 M EDTA and 0.2% SDS. Hybridised RNA resistant to ribonucleases A and T was scored. In panel A samples equivalent to 3×10^7 cells were hybridised to 2 μ g equivalent of Sma1 B, 18.2-36.7, (x) and Sma1 F, 11.1-18.2 (○) per filter. *c*, Nuclei from cells infected with Ad2 for 19 h were isolated^{8,9} and labelled for 2 min with ³H-UTP either with or without 0.5 μ g α -amanitin. Nuclear RNA was extracted, sedimented and hybridised to total Ad2.

the primary transcripts from a single large rightward reading transcription unit⁸⁻¹⁴. The location of the promoter site for this large transcript at 16.45 on the Ad2 genome^{9,15} makes an assay for the frequency of transcription of the beginning of this transcription unit compared to the transcription of the remainder of the region possible. (The linear Ad2 genome is divided into 100 units of 355 bases each with 0 at the left end of the DNA strand that is transcribed to the right.) This assay utilises labelled 'nascent' RNA (unfinished chains labelled only at their growing ends^{8,9,16,17}) hybridised to appropriate Ad2 fragments produced by restriction endonuclease digestion. From the present experiments it appears that as many as 70-80% of the RNA polymerase molecules that initiate Ad2 RNA chains at 16.45 fail to continue for more than ~2,000 nucleotides. The polymerases that are responsible for producing the primary transcripts from which the majority of the late Ad2 mRNA is derived continue to ~98.5, a distance of ~29 kilobases^{8,9,14-16,18,19}.

If cells or isolated nuclei are exposed very briefly to labelled RNA precursors, the labelled RNA chains from a single transcription unit will form an equimolar series of nascent chains labelled at their growing 3' termini^{8,9,16,17}. All chain lengths between very short polynucleotides and the finished length should be equally labelled if no premature termination and no processing occurred during transcription. Figure 1c shows that Ad2-specific RNA labelled *in vitro* in nuclei isolated from Ad2 infected cells presented a bimodal distribution of Ad2-specific chains. A broad continuous distribution of Ad2-specific RNA from about 2–20 kilobases was observed with a peak sedimenting faster than 45S pre-ribosomal RNA (14 kilobases). Also, a distinct peak of shorter Ad2-specific RNA that sedimented about equally to 18S (~2 kilobase) rRNA was observed. This result repeats that of an earlier experiment⁸, where it was further shown that the 10–18S *in vitro* labelled Ad2-specific RNA was complementary mainly to DNA fragments 11.1–18.2 and 18.2–36.7, that is, to regions near the start site (16.45) for late Ad2 RNA synthesis. To test whether the same pattern of transcription also occurred *in vivo*, 'late' Ad2-infected HeLa cells were labelled with ³H-uridine for 45 s. The nuclear RNA was isolated and separated by sedimentation and the various sized RNA chains were hybridised to Ad2 DNA. Two experiments are shown in Fig. 1a, b. In both a bimodal distribution of large (~45S pre-rRNA) and small (~18S and less) Ad2-specific RNA sequences was observed. In approximately five *in vivo* experiments the sedimentation pattern of Ad2-specific RNA was similar. The amount of 'short' Ad2-specific RNA varied from a peak about one-half as great as the large RNA to approximately twice as great as the large Ad2 RNA.

To determine the origin of the short *in vivo* labelled Ad2-specific RNA the 6–18S region from one *in vivo* labelled preparation was pooled and hybridised to a series of fragments of the Ad2 genome prepared by restriction endonuclease digestion (Table 1). Over 75% of the smaller Ad2-specific chains hybridised to DNA fragments 11.1–18.2 and 18.2–36.7 that contain the first part of the transcription unit, in accord with the *in vitro* result^{8,9,15}. Most of the remainder of the small RNA hybridised to the 3–11 region where two or three independent transcription units are known to exist^{9,20,21}. If every polymerase which started at ~16 continued through the entire major late transcription unit (to a terminus near ~99 (ref. 19)) the distribution of labelled chain lengths would be unimodal in a sucrose gradient. The bimodal distribution with an enrichment

Table 1 Hybridisation to Ad2 DNA restriction fragments of small (10–18S) *in vitro* labelled RNA

Coordinate of DNA fragment	c.p.m. hybridised	% Total

83.4–89.7	70	

³H-uridine labelled RNA of ~6–18S (equivalent to fractions 21–27 in Fig. 1a, b) was collected from cells that were pulse-labelled (45 s) at 18 h post-infection (see Fig. 1). The input was equal to the 6–18S RNA from 2×10^7 cells. Three successive rounds of hybridisation were carried out to DNA filters containing 10 µg equivalent of each fragment (that amount of a given fragment that would be contained in 10 µg of total Ad2 DNA). The hybridisation was for 48 h at 65 °C in $2 \times$ TES (0.01 M N-tris(hydroxymethyl)methyl-2-aminoethane sulphonic acid, 0.01 M EDTA, 0.2% SDS)²⁷. After the first round of hybridisation the supernatant solution was withdrawn and the filters were washed twice at 65 °C with $2 \times$ SSC (standard saline citrate; 0.15 M NaCl, 0.01 M Na citrate). All the unbound RNA was collected by precipitation with ethanol and the second round of hybridisation was carried out. The third round was then performed. Approximately 60% of the hybrids formed in the first round, 30% in the second round, and 10% in the third round.

of sequences complementary to the promoter proximal regions of the transcription unit is evidence that premature RNA chain termination occurs after about 1,000–2,000 nucleotides both *in vitro* and *in vivo*.

To determine the frequency of premature termination the amount of RNA synthesised in 45 s that was complementary to a variety of DNA fragments was measured. The amount of labelled RNA complementary to any DNA fragment divided by the length of the fragment that is transcribed is a measure of the 'molar' amount of RNA synthesised from that DNA region^{8,9,14}. The length of the 11.1–18.2 region that is transcribed was taken to be 600 nucleotides, from 16.45 to 18.2, the distance from the presumed promoter to the end of this fragment¹⁵. All of the other fragments except the terminal fragments 89.7–100 were

Fig. 2 Two-dimensional oligonucleotide analysis of RNA hybridised to the 11.1–18.2 region of Ad2 DNA. Ad2-infected HeLa cells were labelled with ³²P (2×10^8 cells were exposed to 50 mCi carrier-free ³²P-orthophosphate 14–18 h after infection) or nuclei from infected cells were prepared 18 h post-infection and labelled by *in vitro* incorporation of [α -³²P]UTP for 2 min⁸. Nuclear RNA was extracted from both samples and the *in vivo*-labelled RNA > 28S was selected by sedimentation. The RNA was hybridised to the Sma1 F DNA fragment 11.1–18.2 using 100-µg equivalent filters per 10^8 cell equivalents, eluted after T1 digestion and extensive washing and fingerprinted as described previously¹⁵. Oligonucleotides labelled 1–5 were eluted and secondary analyses (pancreatic digestion followed by DEAE electrophoresis¹⁵ confirmed that the same sequences were present in the *in vivo* and *in vitro* labelled oligonucleotides. For the *in vitro* labelled sample the extramolarity for Sma1 F, 11.1–18.2, was demonstrated as in Table 2 and 95% of the Sma1 F-specific incorporation was inhibited by α -amanitin.

³H-uridine labelled nuclear RNA was prepared after a 45-s exposure of Ad2 infected HeLa cells (16–18 h post infection) and the total RNA sample was hybridised as indicated to various Ad2 DNA restriction fragments (see Fig. 1 for details). Two or three rounds of hybridisation were carried out in each case.

* The length transcribed, in kilobases, was taken to be the whole fragment except for the 11.1–18.2, *Sma*I F fragment where only 0.6 kilobases from 16.45–18.1 is transcribed^{8,14} and for the 89.7–100 *Eco*C fragment. It is probable that the termination site for transcription is at ~98.5 (ref. 19) and the DNA transcribed in this fragment would be 3.2 kilobases.

† Molarity was calculated by dividing the c.p.m. in hybrid by the length transcribed for each fragment and normalising to 1.0 for 83.4–89.7 fragment which was used in every experiment.

assumed to be completely transcribed. Transcription of the terminal fragment was taken to be 89.7–98.5 (ref. 19). When the molar amount of synthesis from each DNA region was calculated, there was three- to sixfold more labelled RNA complementary to 16.45–18.2 than to any other DNA fragment (Table 2). The remainder of the fragments were essentially equally transcribed, a result which has been obtained in other experiments^{8,14,19}.

In calculating the molarity of transcription from the 11.1–18.2 region an assumption was made that all transcription reads rightward beginning at 16.45. This assumption is justified from previous experiments²¹ that showed 98.5% of total late transcription to be rightward reading. In addition, other recent experiments by Sehgal *et al.*²² showed that 90% of the nuclear RNA labelled in a 2-min pulse that was complementary to the 11.1–18.2 region was complementary to the *r* strand.

Evidence that the short and presumably prematurely terminated RNA contains the same sequences and thus begins at the same site as those molecules that eventually give rise to mRNA is given in Fig. 2. Infected cells were labelled with ³²PO₄³⁻ and nuclear RNA from molecules larger than 5,000 nucleotides was hybridised to the 11.1–18.2 fragment and unpaired RNA digested with T1 RNase. The filters were then washed extensively and the RNA eluted, digested with RNase T1 and fingerprinted. The hybridised RNA (Fig. 2a) revealed the characteristic large oligonucleotides that were previously shown to be near the 5' end of long nuclear RNA transcripts¹⁵. These T1 oligonucleotides were all predicted on the basis of direct sequence analysis to be part of rightward reading RNA molecules beginning at 16.45. As previously reported no oligonucleotides characteristic of sequences to the left of 16.45 were observed¹⁵. For comparison, isolated nuclei which continue synthesis of chains already initiated⁸ and which exhibit premature termination (Fig. 1c) were labelled with [α -³²P]triphosphates, and RNA complementary to 11.1–18.2 isolated. A fivefold molar excess of the *in vitro* labelled ³²P-labelled RNA to the 11.2–18.1 region was detected by hybridisation of a small portion of the preparation to a series of DNA fragments as had been done in the experiments of Table 2 (data not shown). When this ³²P-labelled RNA was bound and eluted from the 11.1–18.2 DNA, subjected to T1 digestion and analysed by fingerprinting, the same characteristic large oligonucleotides as those observed in the *in vivo* ³²P-labelled RNA were most prominent. In addition, many smaller oligonucleotides coincided (Fig. 2). Thus the prematurely terminated chains appeared to start at the same site as the chains that eventually are processed into mRNA. It is not possible, of course, from this experiment to be certain that the same exact 5' end is present on the prematurely terminated

RNA. However, preliminary evidence from *in vivo* labelled RNA (Fraser, Sehgal and J.E.D., unpublished) indicates that the short Ad2 chains that accumulate in a long ³²P label in infected cells have a similar fingerprint as that of Fig. 2 and contain the same capped oligonucleotide characteristic of the large late transcription unit.

Thus, the major result of the present experiments is that three to six times as much transcription occurs, presumably beginning at 16.45, as in other regions of the large late transcription unit. The sucrose sedimentation of pulse-labelled RNA (Fig. 1a, b) suggested that the extra transcription could continue as far as 2,000 nucleotides and this conclusion was also supported by the hybridisation of the slower sedimenting second peak of Ad2-specific RNA mainly to the 11.1–18.2 and 18.2–36.7 DNA fragments (Table 1 and Fig. 1a). From the present data we cannot conclude whether there are specific termination sites. The extra-molar synthesis does not extend past 25.5–27.9 because pulse-labelled RNA complementary to this region was earlier shown to be equimolar with all other regions to the right of 25 (refs. 8, 14). Thus the third of the leader sequences at 26.7 that is spliced to late Ad2 mRNAs^{11–13} does not appear to be represented in the extra synthesis, although each late mRNA is believed to contain all three leader sequences^{6,11–13}. Furthermore, it seems very unlikely that the prematurely terminated chains lead to production of mRNA molecules containing sequences that lie exclusively within the first 2,000 nucleotides of the transcription unit. Extensive searches for mRNA:DNA duplexes by electron microscopy^{6,11} have not revealed mRNA that lies within the 16–25 region and fingerprint analysis of cytoplasmic RNA does not show the distinctive oligonucleotides of Fig. 2 which lie within the first 500 nucleotides of the transcription unit¹⁵. Thus very few if any of the extra-molar premature transcripts appear as stable mRNA in the cytoplasm.

One final point concerns the nature of the enzyme responsible for the short prematurely terminated RNA chains. In the experiments of Figs 1 and 2, a portion of the isolated nuclei during incorporation of labelled precursor was treated with 0.5–1.0 μ g ml⁻¹ of α -amanitin, a dose of this inhibitor that almost completely inhibits synthesis by RNA polymerase II but not RNA polymerases I or III (ref. 23). The synthesis of >90% of the Ad2-specific RNA, both short chains and long chains, was sensitive to α -amanitin (Fig. 1c, legend to Fig. 2). Therefore, it seems that it is RNA polymerase II that prematurely terminates RNA chains within the first 2,000 nucleotides of the large Ad2 transcription unit. Other recent studies have shown that polymerase II transcription termination also frequently occurs in cell heterogeneous nuclear RNA formation (ref. 26, M. Salditt-Georgieff, M. Harpold and J. E. D., in preparation).

Transcription termination as a regulatory mechanism has been extensively documented in the temperate bacteriophages^{24,25} in addition to the attenuation phenomenon in the amino acid operons in *Escherichia coli*¹⁻⁴. In these instances the frequency of termination is very high, occurs on a region immediately preceding structural gene clusters and probably involves interactions between ribosomes translating the new 5' terminus of the RNA chain and the polymerase molecule that is synthesising the RNA chain. If there is any regulatory role at all for premature termination on mammalian cell or Ad2 DNA it would be unlikely to involve ribosomal interaction with growing chains of RNA in the nucleus of a mammalian cell and so no mechanism of premature termination parallel to bacterial attenuation seems likely. A cause for premature RNA chain termination other than a direct regulatory role might be found in reports about the complexity and steps of Ad2 mRNA formation¹⁴. Based on the close linkage in time between transcription, selection of a site and addition of poly(A), polymerase II may be accompanied by processing enzymes or may possess processing subunits¹⁴; possibly if polymerase-processing complexes that initiate transcription are incomplete they may be rejected after a certain distance from the origin of transcription.

Sequence of three introns in the chick ovalbumin gene

WE now know that many genes are split, that is, that the DNA is not co-linear with its RNA, but is interrupted by regions of DNA about 10-1,000 residues long which have been called intervening sequences or introns¹. This organisation poses special problems for the biosynthesis and processing of mRNA², but is widespread in occurrence³⁻¹⁷, although some genes are known not to be split^{18,19}. Little is known of the detailed sequence of introns. In the case of globin and ovalbumin genes, hybridisation experiments^{20,21} indicate an absence of extensive sequence homology with other unrelated genes. Detailed sequence analysis of the β -globin genes in mice and rabbits²² suggest that during evolution introns diverged in sequence and in length

Fig. 1 Arrangement of introns (light, A-G) and exons (dark, I-VIII) in the chick ovalbumin gene. The positions of the cloned 1.8, 2.4 and 9.5 kilobase fragments separated by *EcoRI* restriction sites are shown. The 5' *EcoRI* fragment containing exon I has not yet been characterised so that the length of A is unknown.

more rapidly than the expressed sequences or exons, although the position of the exon-intron junction is precisely maintained²². The ovalbumin gene is a particularly extreme example of an interrupted gene. It has seven introns, and is spread over a distance of at least 6 kilobases (Fig. 1), but this distance is compressed at least 7 times into less than 800 residues of mRNA sequence; all seven known splice points occur between residues 47 and 830 in the 5' half of the ovalbumin mRNA^{23,24}. This gene is thus a favourable model gene for studying both the general properties of introns and the mechanism of splicing. Previously we and others sequenced selected short regions in two cloned fragments (the 1.8 and 2.4 kilobase fragments) of the gene to define the possible recognition site of the presumed splicing enzyme^{24,25}. We now report the sequence analysis of three introns of the 2.4-kilobase fragment of the chick ovalbumin gene.

A clone of the 2.4-kilobase ovalbumin fragment (pOv2.4) contained within the plasmid pBr322 and the vector *Escherichia coli* had been previously isolated and the major restriction sites mapped^{23,26}. After transfer of the pOv2.4 to *E. coli* RRI suitable restriction fragments were prepared which were labelled either at their 5' or 3' ends with ³²P for sequencing by the chemical degradation method of Maxam and Gilbert²⁷. Figure 2 summarises the sequence evidence and the legend gives details of some technical improvements in the methods. It can be seen that most of the sequence was read off both strands of DNA to ensure 100% sequence accuracy. Where data from one strand were

There are no sites for *HaeII*, *HhaI*, *HpaII*, *HgaI*, *AvaI*, *BamHI*, *BglII*, *SmaI*, *Sall*, *TaqI* and *XhoI*. *EcoRI* sites define the two ends of the fragment. The residue number given is the first (5') nucleotide of the recognition sequence and not the point of cutting. Where this is within the recognition sequence it is indicated by a vertical bar.

* These enzymes fail to cut pOV2.4 grown in *E. coli* strain RRI because of methylation of C(*EcoRII*) or A(*MboI*) residues (see text).

† See Roberts²².

Fig. 2 Diagram of gel evidence showing the overlapping data used to derive the sequence of the 2.4-kilobase fragment (represented by the coding strand 5'-3', left to right). Lines indicate the length of sequence read and the restriction enzyme used to prepare the fragment. Above, the sequence was of the coding DNA strand; below, the sequence of the complementary non-coding strand. Arrows point away from the labelled position. 5'-labelling with ^{32}P was carried out with $[\gamma\text{-}^{32}\text{P}]\text{-ATP}$ and T4 polynucleotide kinase²⁸ using restriction fragments derived by *Eco*RI, *Hpa*II, *Pvu*II, *Mbo*II, *Hinf*I, *Hph*I and *Alu*I digestion of either the purified 2.4-kilobase ovalbumin gene fragment (purified by 3.5% acrylamide gel electrophoresis²⁸) or the intact pOv2.4 plasmid directly, so as to obtain higher yields of labelled fragments. 3'- ^{32}P -labelled, *Eco*RI and *Hinf*I labelled fragments were also prepared by 'filling in' with a single $[\alpha\text{-}^{32}\text{P}]\text{dATP}$ using the Klenow fragment of DNA polymerase I (*E. coli*) (F. Sanger and J. Hindley, personal communications). Complementary strands in the size range of 20–200 residues were separated by heat denaturation in formamide and electrophoresis on 20% acrylamide 7 M urea gels (G.G.B., unpublished). Separated strands or labelled fragments, recut by another restriction enzyme, were subjected to chemical modification according to Maxam and Gilbert²⁷ using the alternate G, alternate A, C and C+T degradation and fractionation on an 8% or 20% acrylamide, 7 M urea thin²⁹ gel (0.3 × 200 × 400 mm). Longer (800 mm) thin gels (8%) were used to 'read' sequences 200–300 residues from the site of labelling. Sensitive autoradiography was according to Laskey and Mills³⁰. All the exon sequence was established independently of the mRNA except: (1) 10 residues across the *Hinf*I overlap (residue 766) in exon III; (2) 60 residues between the *Hph*I site (1,425) and *Mbo*II site (1,478) in exon IV; (3) 10 residues across the *Pvu*II site in exon V. A computer file was kept on the sequence as different restriction fragments were sequenced and this was edited using the SEQEDT program of Staden³¹, as new data became available. The file was also routinely searched for possible restriction sites³¹.

Fig. 3 Sequence of 2.4-kilobase fragment. The exons II–V and introns A–E are identified, as are the boxed regions showing terminal redundancy at each end of the introns. Arrows indicate the predicted splice points (see text).

Table 2 Simple parameters of the 2.4-kilobase sequence

Region (Fig. 3)	Length (no. of residues)	A + T%	CG (frequency)	AA (frequency)
A*	304	63	1	30
B	251	64	0	28
C	581	62	3	81
D	400	68	3	49
E*	349	59	1	31
II	185	54	1	16
III	51	58	2	3
IV	129	57	2	11
V	118	56	0	13

*Introns A and E are incomplete, so that the length and other parameters quoted here reflect only the proportion of these introns present in the 2.4-kilobase fragment.

used, only completely clear gel evidence was used to construct the sequence. A single arrow was invariably constructed from many independent gels.

The restriction enzymes *Mbo*I and *Eco*RII failed to cut the recombinant plasmid grown in *E. coli* RRI because of a methylation of the A residue (in the sequence GATC) or the second C residue (in the sequence CC(A/T)GG (ref. 28)). An anomalous degradation was also present in the sequencing gels, in that 6-methyl A gave a weaker band than an unmodified A in the alkaline degradation (alternate A) procedure²⁷. Similarly, 5-methyl C was resistant to hydrazinolysis, resulting in possible misreading of the gel¹⁹. Therefore, in all such cases of possible ambiguity the sequence was carefully checked on the opposite strand of the DNA.

Figure 3 shows the sequence of the 2,368 residues present in the 2.4-kilobase fragment, and Table 1 gives the position of most of the known restriction sites within this sequence. The exon sequences are underlined in Fig. 3 and were identified by their presence in the mRNA. It codes for 26% of the mRNA, from residue number 48 to 530, out of a total of 1,859 residues²⁸. No differences were found in these regions between the gene and the previously determined mRNA sequence²⁸, although about 80 residues of exon were not established independently (see legend to Fig. 2). Figure 3 indicates the previously noted terminal redundancy at each end of the introns B, C and D and the predicted splice points^{24,25}, either before or after a GT or AG doublet, depending on which end of the intron it is. A general summary of properties such as the length, base composition, expressed as % A+T, and frequency of CG doublets relative to AA doublets are given in Table 2. This shows that the three complete introns (B, C and D) vary by 251–581 residues in length. Exons are remarkably short; the smallest, exon III, is only 51 residues. The entire sequence is A + T rich, but is slightly higher for introns (varying by 62–68%) than for exons (54–58%). CG doublets occur very infrequently (compared with AA doublets) in the exons, as noted before²⁸, and also in all introns. No other doublet behaves like CG.

The main purpose of the sequence analysis of this part of the ovalbumin gene was to focus on introns. We have sequenced three introns completely and in all, nearly 1,900 residues of intron sequence are presented here. We had hoped to find specific primary sequence or secondary structures which might give an insight into the mechanism of RNA splicing. However, despite extensive computer analysis, we have been unable to find any convincing features. We will therefore defer presentation of this analysis until the full structure of the gene is known.

Solar modulation of atmospheric electrification and the Sun-weather relationship

MARKSON¹ has provided a useful summary of reasons for looking to atmospheric electrical structure for an explanation of 'Sun-weather' correlations, but the specific global and local mechanisms which he proposes do not, in the light of available evidence, apparently produce such effects frequently enough to explain the observations. Effects more directly related to magnetospheric and auroral phenomena would seem to show more promise in explaining the observed coupling of solar activity to lower atmosphere electrical phenomena.

The global effect proposed by Markson is that the 'Forbush decrease'² in cosmic ray intensity associated with solar flares results in a decrease of atmospheric ionisation with consequent effects on the 'global circuit'. Measurements made on a high mountain by Reiter³ have shown that the fair-weather electric field and current show 10–30% effects related to solar magnetic sector boundary crossings. Forbush measured decreases of the order of 1% at low latitudes and even at higher altitudes and latitudes, the effects rarely exceed a few per cent.⁴ As Markson points out atmospheric conductivity is expected to vary as the square root of the Forbush decrease, (ionisation rate) it is difficult to see how this mechanism could produce the observed effects, as decreases of the order of 50% in cosmic ray flux at low latitudes would be required.

The local effect proposed by Markson involves the direct penetration of ionising radiation effects to the tops of thunderclouds, (~20 km at mid and high latitudes). While this is perhaps possible in some rare solar proton (PCA) events⁵, such as the large flare of August, 1972, there is little evidence that substantial conductivity variations occur as low as this after more modest events. Yet balloon measurements at high latitudes^{6,7} typically show a 30% increase in the vertical field following geomagnetically disturbed periods. Thus it would seem that we must look for effects more directly related to magnetospheric and auroral processes to explain the reported data. One problem

would seem to be Markson's acceptance of the 'classical picture' of atmospheric electricity, where an 'equipotential surface is considered to exist at about 60 km', which does not allow the penetration of higher altitude electrical effects. The earliest rocket-borne conductivity measurements in 1950 (ref. 8) showed that the classical exponential increase of conductivity did not persist above 40 km, a result attributed to aerosol particle layers which has since been frequently confirmed⁹. Mühleisen⁷ has observed horizontal electric field gradients totalling ~100 kV between high and mid latitudes following magnetic disturbances, and Tyutin¹⁰ in the USSR has reported a 'permanent' mesospheric vertical field of similar magnitude. (We have tentatively confirmed the USSR measurements and suggested that the 'shorting out' of the vertical field by ionisation produced by aurorally related radiation might produce local changes in the lower atmosphere vertical field and also the observed horizontal potential differences, by adding the permanent mesospheric potential to the lower atmosphere circuit at high latitudes¹¹.) These measurements clearly demonstrate the invalidity of the classical picture for studying many possible coupling mechanisms.

Other promising avenues of investigation would seem to be the direct 'mapping' of ionospheric fields to low altitudes¹² and of aurorally produced charge separation¹³ inducing displacement currents and electric fields in the lower atmosphere. Magnetospheric and auroral phenomena would seem to have a chance of explaining the 22-yr 'magnetic cycle' Sun-weather effects cited by Markson, because of the likelihood that they could be influenced by the details of the solar magnetic field structure. An intermediate mesospheric coupling circuit modulating the lower atmosphere circuit would have the attractiveness of providing a mechanism responsive to auroral particles or bremsstrahlung rather than requiring rare high intensity events, and could thereby provide a more prevalent coupling effect due to the much greater frequency of such events.

MARKSON REPLIES—Hale's objection may be summarised as: (1) he does not believe that the requisite changes in ionisation occur; nor (2) that the classical picture of atmospheric electricity is valid. He is inaccurate in his quotation and citation, and there is some question regarding his interpretation of data and their significance.

I wish to point out the following: conductivity variations occur sufficiently low in the atmosphere and frequently enough to be a significant factor in solar modulation of current flow in the global circuit. Hale refers to relatively small changes in the galactic component of cosmic radiation measured on the ground which are not representative of the much larger variations of ionising radiation in the lower stratosphere. Winckler¹, in summarising his balloon program in which cosmic rays were measured at mid-latitude (Minneapolis) states "Probably the single most significant finding of the entire series (of flights) was the frequent occurrence of intense low energy cosmic rays. They originated from large solar flares but had energy spectrum so steep that the particles were not detected by the extensive network of sea-level cosmic ray monitors established during IGY. The particles were measured directly, however, by means of balloons at altitudes greater than 20 or 25 km". Not only are solar controlled changes in ion production larger and more frequent in the 20–30 km height range compared to near the Earth, they generally are of the opposite sense, increases instead of decreases^{1–3}. Akasofu and Chapman⁴ (Hale's reference) discuss three Forbush decreases in a 16-day period which resulted in a cumulative 20% reduction in cosmic ray rate at the

Earth's surface. During this interval, Winkler's balloons³ recorded 2–10 fold increases in ion production rate at 24 km, half an electrical scale height above 20 km. Such events, if they were over 20 km high thunderstorms, would at least double the current flow from them. There is also a long period variation in cosmic radiation which is inversely correlated with the sunspot cycle⁵. My Fig. 1, averaged data from Neher and Anderson⁶, illustrated that through a solar cycle at 15 km (100 g cm^{-2}) ionisation increases 51% (conductivity 23%) while at 20 km (50 g cm^{-2}) ionisation increases 76% (conductivity 33%). While these data are for high latitude, Fig. 4 in my article⁷ depicts the variation with latitude of ion production at 20 km. At mid-latitude the conductivity variation through a solar cycle is $\sim 18\%$, near the Equator it is $\sim 10\%$. As these are average values, larger variations must occur at times.

Changes in fair-weather electric field intensity (a measure of ionospheric potential) related to solar sector crossings⁸ does not imply that the electric field is controlled through geomagnetic processes. However, thunderstorms (which maintain the ionospheric potential) have been found to vary with solar sector crossings^{9–11}.

Almost all students of atmospheric electricity accept the general premises of the classical global circuit concept because there is strong evidence supporting this view^{12–15}. As fair-weather electric fields vary simultaneously all over the world and correlate with the universal time variation of global thunderstorm activity^{16,17}, even in the polar cap region¹⁸, upper atmosphere generators (which follow local time) can not be the cause of the ionospheric potential. In addition, the latter would not vary simultaneously over large distances¹⁷ unless the ionosphere had the characteristics of an equipotential surface. It is well known that potential differences can exist across the auroral oval; this does not invalidate the classical picture which is necessary to explain the maintenance and characteristics of the Earth's electric field at sub-auroral latitudes, that is over 85% of the Earth's surface (including most of the portion with thunderstorms). Satellites that record 70–200 kV across the auroral oval do not measure significant potential differences between the auroral zone and mid- to low-latitudes (R. G. Roble, personal communication). Magnetospheric electric fields impressed in the polar ionosphere are attenuated to 10% of their high-latitude value by mid-latitude¹⁹.

The proposed mechanism⁷ does not depend on 'Forbush decreases', this is a generic term used to describe decreases in galactic cosmic radiation following some solar flares. Conductivity, of course, does not vary as the square root of Forbush decreases.

Hale erroneously believes the proposed

mechanism requires a 50% decrease in cosmic ray flux at low latitudes although my article discusses effects on thunderstorm currents at all latitudes and does not mention a 50% decrease in cosmic rays. Perhaps he is referring to the increase in ionising radiations causing a 50% decrease in columnar resistance over the 'global generator' that I used for arithmetic simplicity to illustrate the sensitivity of the entire global circuit to conductivity changes within the small volume over thunderstorms.

The average ground level Forbush decrease is 5% (with a maximum of 20%), not the 1% implied by Hale²⁰.

While the August 1972 flare was unusual in having a very high number density of low to moderate energy particles, numerous other flares have had a larger density of particles in the high energy end of the spectrum²¹. The latter particles penetrate deepest into the atmosphere and cause the effects under discussion.

Ionising radiation does not have to reach the tops of thunderclouds to increase the current flow from them to the ionosphere; it only has to lower the total columnar resistance over the clouds. If, however, ionising radiation did reach the cloudtops, cloud electrification might be enhanced²². Increased ionisation following solar flares has been reported in the 15–20 km height range^{2,3,23}.

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 300 words and the briefest of replies, to the effect that a point is taken, should be considered.

Tyutin's rocket measurements²⁴ (evidently similar to ones made by Hale) indicate that the fair-weather field reverses above 10 km. It is surprising that Hale accepts such data which are contrary to fundamental physical principles. As the vertical air–Earth current is unidirectional from the ionosphere to Earth, electric fields at all heights must be of the same sign.

Concerning aerosol layers above 40 km, such conditions would have little effect on atmospheric electricity in the

lower atmosphere unless the columnar resistance through this upper atmospheric region were a significant fraction of the columnar resistance through the lower atmosphere. There are no measurements indicating that such conditions exist.

Hale cites Akasofu and Chapman⁴ as saying that even at high altitudes and latitudes Forbush decreases rarely exceed a few per cent. This statement is not only erroneous^{1–3}, but it does not appear in the book. Hale's ref. 13 is a paper by Cole and Pierce, not by Freier.

An attempt to explain solar–weather relationships as due to ionospheric and magnetospheric electrical processes is understandable, however, these do not seem applicable to the problem. Upper atmospheric currents and particles would introduce energy into the atmosphere orders of magnitude too small to affect weather processes^{25,26}. They would be important to the extent they influenced thunderstorm currents and cloud electrification in the lower atmosphere⁷.

inserm

IMMUNIZATION OF CHILDREN

INSERM Vol. 79, 440 pages / 80FF / 20 US dollars air mail postage included
46 contributions, 31 in French with summaries in English, 15 in English

Proceedings of the symposium organised in June, 1978, by the French National Institute of Health and Medical Research (INSERM), the International Children's Centre (I.C.C.) and the W.H.O.

Edited by Dr Colette FILLASTRE (I.C.C. Epidémiologic Pilot Station, France) and Dr Jeffrey EDSALL (University of California, La Jolla, U.S.A.)

This book presents current developments in vaccines, bacterial and viral (new vaccines, laboratory controls), immunization techniques, planning and fulfilment of national immunization programmes, deals with ethical and epidemiologic problems and makes suggestions on how to apply the use of basic research to public health.

5 sessions with bilingual syntheses by:

Frank Perkins (W.H.O. Geneva, Switzerland); Ph. Lagrange (Paris, France), Hanz Cohen (Bilthoven, Holland); Helio Pereira (Pirbright, Woking, G.B.), J. A. Dudgeon (London, G.B.); Colette Fillastre (Paris, France) and Michel Rey (Clermont-Ferrand, France)

200 YEARS OF ASTRONOMICAL ANOMALIES

IDENTIFICATIONS

1. Zodiacal light with spurious lobe. 2. Color phenomena (shaded areas) in lunar crater. 3. Distorted shadow during lunar eclipse. 4. Radial spokes on Venus. 5. Planet shadow with "wrong" curvature on Saturn's rings. 6. Sketch of ring of Uranus seen in 1847.

DATA SOURCES

The complete files of *Nature*, *Science*, *Sky and Telescope*, *Observatory*, *Monthly Notices*, *Popular Astronomy*, *J. Brit. Astro. Assn.*, and others. Over 1000 volumes surveyed.

HUNDREDS OF OTHER PUZZLING ASTRONOMICAL PHENOMENA ARE DESCRIBED IN THIS UNIQUE, PROVOCATIVE NEW BOOK, INCLUDING:

- Dark eclipses
- Lunar dust storms
- Life chemistry in space
- Solar-system resonances
- Ephemeral earth satellites
- Knots on Saturn's rings
- Martian light flashes
- Eclipses affect pendulums
- Planets and sunspots
- Bright objects near sun
- Cosmological paradoxes
- Ashen light of Venus
- Erratic meteors
- Jumping stars
- Lunar lightning
- Decelerating light
- Moon of Venus
- Double shadows of Jovian satellites

MYSTERIOUS UNIVERSE: A HANDBOOK OF ASTRONOMICAL ANOMALIES

Compiled by
WILLIAM R. CORLISS

- 700 pages of source material
- Over 100 illustrations
- 500 authoritative articles and eye-witness accounts
- Hard-to-find data
- Casebound, rugged

H. E. Huxley, MRC Laboratory of Molecular Biology, Cambridge

S. V. Perry, Department of Biochemistry, Birmingham University

J. W. S. Pringle, ARC Unit of Muscle Mechanisms and Insect Physiology, University of Oxford

The **Journal of Muscle Research and Cell Motility**, has as its main aim the publication of original full-length research papers on any aspect of muscle, contractile mechanisms or cell motility. As research in this area embraces a very wide range of disciplines and techniques the policy of the journal is to encourage any form of practical study whatever its specialist interest, provided only that it contributes to a greater understanding of the way that muscle contracts or cells move. Theoretical essays will also be welcome as long as they are concise and suggest practical experiments by which an idea may be tested. Review papers, book reviews, announcements and reports of meetings may also appear from time to time at the discretion of the Editors. The language of the journal is English. An international panel of advisory editors is being appointed.

Editorial Enquiries

Intending authors are welcome and should write in the first instance to one of the principal editors, who will supply detailed information on the preparation of manuscripts.

Subscription Information

Four issues a year commencing January 1980.

Approximate subscription rates:

UK,	£32.50
USA, Canada and Mexico	£39.50
Other export territories	£37.50
Single Copies	£10.00

Exploration of the Solar System

J. Veverka

The Realm of the Terrestrial Planets.
By Z. Kopal. Pp. 223. (The Institute
of Physics: Bristol, UK, 1979.) £7.50.

THIS book is described as a completely up-to-date account of recent advances in the exploration of the Solar System. Written by a well known astronomer who has made important contributions to our understanding of the Moon and the Solar System, the book is well illustrated and pleasant to read. Unfortunately, it abounds in factual errors. From the nature of most of these, it is clear that the author is writing about the Solar System based on information available, for the most part, a decade ago. It is certainly not an up-to-date account of our current understanding of the terrestrial planets, and is especially dangerous to the initiated reader who has no way of distinguishing fact from error.

The factual errors are too numerous to list in detail. For example, in one single chapter, which consists of 39 pages, there are more than a dozen serious factual errors, not to mention an equally large number of potentially misleading and inaccurate statements. For instance, there is much confusion about the polar caps of Mars. Even though recent Viking results are alluded to, no distinction is made between the annual CO₂ frost caps which form every year and disappear during spring and summer, and the permanent (or residual) polar caps, which survive through the Martian summer. In fact, on page 114, we find a restatement of the old misconception that the southern polar cap of Mars vanishes completely on occasion during summer. It is now known that, although the annual cap is composed of carbon dioxide, the residual caps consist of vast deposits of frozen water, a fact apparently unknown to the author. He is unaware of the fact that even the annual caps can have substantial thickness in places because we read on page 119 that the snowfields in the Martian polar regions must be "less than a few centimetres deep", although numerous studies in recent years have shown that several metres of frost can be deposited in the polar regions during Martian winter.

On page 124, we find further evidence of a thorough misunderstanding of Viking data. It is stated the

Martian sky appears pink in daytime, but that it is blue near sunset and sunrise. There is no evidence to support such an assertion, or the claim that the atmosphere is dust free after sunrise but becomes dusty as the sun rises higher and convection begins to lift up surface dust. Published analyses of the Viking Lander data by Pollack and others clearly demonstrate that the dust does not settle out of the atmosphere daily, but remains suspended for periods on the order of the Martian year. There is no evidence in the Viking data to substantiate the statement made on page 125 that a significant number of dust particles are stirred and lifted into the atmosphere by diurnal convection.

On the same page, there is further evidence that the author has not kept abreast of Mars studies in the last seven years. He states that:

"While the bright markings were identified correctly with arid desert plains and their colour ascribed to that of ferric oxides long before the Viking Landers provided the final proof, the dark markings were thought to owe their lower reflectivity to moisture and even to vegetation flourishing in the spring and watered by systems of canals, natural or artificial from the melting polar caps. Their seasonal variations were regarded as indications that at least plant life existed on this planetary neighbour of ours. These expectations were destined to total disappointment by the outcome of the Viking missions."

This is an astounding statement! Soon after the first Mariner 9 pictures were analysed in 1971-72, it became clear that there is no vegetation in the dark areas of Mars, and that seasonal variations are due to the redistribution of dust, by Martian winds. Similarly, at about the same time, Earth-based telescopic measurements by McCord and others clearly demonstrated that the dark areas of Mars are dark because they are less oxidised than the bright areas. No one in the last seven years has proposed seriously that the dark areas are dark either because of moisture, or because of vegetation.

There are several indications that Kopal does not believe or is not convinced that the large structures such as Olympus Mons are really volcanoes. Although one could sympathise with such a cautious attitude, it is much more difficult to take kindly unsupported statements such as that the

whole of Olympus Mons is not more than 10 Myr old.

Perhaps the most colossal blunder in the entire chapter involves sinuous channels. Kopal shows a Mariner 9 picture of some faults on Mars which have never been called 'sinuous channels' by anyone, except Kopal, and have never been attributed to erosions by liquid water by anyone. On the following page, he shows an example of similar features on the Moon and writes, "Note the striking similarity between these lunar features and those on Mars as shown in the previous plate. The origin of these features on the Moon has nothing whatever to do with water". Kopal cautions the reader "against jumping to conclusions about erosion caused by flowing water. For whatever may be a merit of such a suggestion as regards to Mars, it certainly would not apply to the Moon". The whole argument is embarrassing. Nowhere does Kopal show a real Martian sinuous channel. Of course, linear faults were not produced by flowing water.

One should not get the impression that the Mars discussion is the only one marred by serious errors. For example, the discussion of the Mars satellites, Phobos and Deimos, covers only five pages, but contains at least four serious errors. The largest crater on Phobos is not 3 km across; Phobos is not the darkest body in the Solar System: grooves on Phobos most likely do not represent the effects of "cosmic abrasion"; and it is certainly not true that such grooves are "also characteristic of certain parts of the Moon".

There is little point in picking apart other chapters in similar detail—most contain similar serious factual errors and misconceptions.

The Realm of the Terrestrial Planets, although a superficially attractive, well illustrated book, is too full of errors to be recommended to any reader, except as a record of what a noted astronomer thinks the inner Solar System might be like, based mostly on data generally available about ten years ago. It could have been a much more important book if it were really based on current information. □

Joseph Veverka is Associate Professor of Astronomy at Cornell University, Ithaca, New York.

Koobi Fora hominids

The Fossil Hominids and an Introduction to Their Context, 1968-1974. (Koobi Fora Research Project, Vol. 1). Edited by M. G. Leakey and R. E. Leakey. Pp. 191. (Clarendon/Oxford University Press: Oxford, 1978.) £15.

THIS is the initial volume of a projected series of monographs on interdisciplinary earth sciences and palaeoanthropological researches in the Koobi Fora area, northeastern Turkana basin, Kenya. That combined research effort unquestionably represents one of the most lastingly important and fruitful investigations into the earlier evolutionary history of Hominidae and the natural setting and biotic associations of Plio-Pleistocene times. This volume provides an historical and methodological introduction (R. E. Leakey); followed by chapters on geology, palaeontology, archaeology and fossil hominids.

A summary of the lithostratigraphy, sedimentary environments and palaeogeography of the Kubi Algi and Koobi Fora formations is provided by I. C. Findlater. This chapter sets out the stratigraphical nomenclature now used for these formations, the members of which are defined on the basis of several spatially extensive tephra. Five principal sedimentary environments are recognised, two lacustrine and three alluvial; and their areal relationships are shown diagrammatically. Eight generalised maps depict palaeogeographical settings of the area of successive temporal intervals during the accumulation of the Koobi Fora Formation. Maps show the locations of the principal hominid finds in the major fossiliferous areas; their temporal relationships and environments of deposition are indicated in stratigraphical section and usefully summarised in a table.

An annotated inventory (and listing) of 87 mammal taxa (exclusive of micromammals) in those formations, as well as mollusc assemblages and their concurrent range zones, and notes on other vertebrate groups is given by J. M. Harris. The fauna of the Kubi Algi Formation is not specified, but is stated to overlap in part that of the (lower) portion of the Koobi Fora Formation. The Ileret, Koobi Fora and Kubi Algi sectors have been each subdivided into a series of numbered areas (19 in the former two, 5 in the latter) for purposes of geological mapping and fossil collection. Tephra deposits are widespread, some demonstrably

spatially extensive and useful in correlation. Certain (named) tuffs serve as marker horizons to differentiate and to subdivide the several formations; however, the relationships, spatially and temporally, of many other (numbered) tuffs are uncertain. Three fossil 'collection units' are now recognised for the Kubi Algi Formation, and five such 'units' for the Koobi Fora Formation, the base of each being defined in a particular area by a named or numbered tuff. However, in the Koobi Fora Formation just over half of all fossiliferous areas in the Ileret sector and nearly half of all such areas in the Koobi Fora sector have lithostratigraphically undefined lower boundaries. Thus, the 'collection unit' concept seems to have limited utility at best, as it is an unfortunate mix of both lithostratigraphy and biostratigraphy.

An overview of the stratigraphical and areal situation, depositional environments and associations, and nature of all major archaeological occurrences, and their content and industrial characteristics is provided by G. L. Isaac and J. W. K. Harris. The

remainder of the volume comprises a well-illustrated inventory, with data on finder, provenience and depositional environment (including many microstratigraphic sections) of all fossil hominids (numbering 129) recovered in the seven years of the project, until 1974 (R. E. and M. G. Leakey and A. K. Behrensmeyer), complemented by an appendix of 30 tables of assorted measurements of those specimens. The scale on some hominid illustrations is unfortunately incorrect. Hominid taxonomy is only briefly mentioned (p89); but not many workers personally familiar with this vast corpus of fossil material will agree with all the attributions suggested. Finally, there is a full bibliography (through 1976) of the project.

This is an immensely useful, well executed and well produced volume of major import to all students of human evolution.

F. Clark Howell is Professor of Anthropology at the University of California at Berkeley.

Coastal sedimentation

Coastal Sedimentary Environments. Edited by Richard A. Davis, Jr. (Springer: New York and Berlin, 1978.) \$22; DM44.

THIS book is intended as a student text and to provide a background on coastal environments for geologists, engineers, oceanographers and coastal managers. Being a multi-author text means that there are certain differences of approach between the chapters; however, this is offset by the obvious expertise that has been brought to bear. The emphasis is on geological description of the morphological features and of the processes that have been interpreted largely from changes in the morphology and from the analysis of internal structures. The chapters have a review style and frequently, to provide an explanation satisfactory for students, would necessitate lectures tailored to the book, or the student to follow up extensively the quoted papers. An example of this is the very brief coverage of longshore transport, which in itself would warrant a chapter in a more specialist book. The bibliographies are reasonably comprehensive and there are abundant and very good photographs, especially of tidal deltas.

There are chapters on river deltas by L. D. Wright, which particularly concentrates on the processes in the Mississippi delta, and on coastal bays by R. B. Biggs, which actually emphasises suspended sediment in estuaries. There is a particularly comprehensive description of American East Coast salt marshes by R. W. Frey and P. B. Basan, and coastal dunes are described by V. Goldsmith. R. A. Davis describes the beach and nearshore zone, and mesotidal inlets and estuaries are covered by J. C. Boothroyd. The latter concentrates largely on tidal deltas. The final two chapters are by J. C. Kraft on the coastal stratigraphic sequences produced mainly by transgression, and by W. T. Fox on modelling coastal environments.

Virtually all of the examples quoted are drawn from the American East or Gulf Coasts. Consequently the extensive body of European literature is largely neglected, together with such features as high range tidal estuaries and coasts. Nevertheless, this will be a useful addition to texts on coastal sedimentation and should be recommended reading on courses covering coastal geomorphology and sedimentology, as well as providing useful background in a wider range of disciplines.

K. R. Dyer

K. R. Dyer is at the Institute of Oceanographic Sciences, Taunton, UK.

Cloud physics

Microphysics of Clouds and Precipitation. By H. R. Pruppacher and J. D. Klett. Pp.706. (D. Reidel: Dordrecht, The Netherlands, 1978.) Dfl. 85; \$39.

DURING the past decade the major emphasis in cloud physics has been directed away from fundamental microphysical processes—which had hitherto largely dominated the evolution of the subject, and in which progress had been based primarily upon laboratory investigation—to field investigations of larger-scale effects, in which the cloud dynamics are recognised to play a central role. This change of approach has been dictated in part by the development of superior experimental techniques—radar, optical particle samplers, high-speed data processing systems, and so on—and in part by the recognition that the major obstacle to progress has been the absence of comprehensive and reliable observational data. Accordingly, the publication of a textbook devoted exclusively to microphysical processes might appear at first sight to be somewhat anachronistic. In fact, however, I feel that this comprehensive and rigorous critical analysis of current understanding of the physics of the multitude of processes which form the basis of the subject, will be of invaluable assistance to research workers. The classic text in this field for two decades has been Mason's massively authoritative *The Physics of Clouds* (Clarendon Press, Oxford, 1957) but an enormous amount of material has been published since the second edition of this work appeared in 1971, and the small number of generally excellent monographs that have been produced in the intervening years have been insufficiently detailed to take full account of this new work.

The range, tenor and emphasis of the book can readily be appreciated by studying the titles of the chapters which follow the short historical review: microstructure of atmospheric clouds and precipitation (the only chapter concerned predominantly with field observations); the structure of water substance; equilibrium between water vapour, water, aqueous solutions and ice in bulk; surface properties of water substance; equilibrium behaviour of cloud drops and ice particles; homogeneous nucleation; the atmospheric aerosol; heterogeneous nucleation; hydrodynamics of single cloud and precipitation particles; cooling of moist air; mechanics of the atmospheric aerosol; diffusion growth and evaporation of water drops and ice crystals; cloud particle interactions—collision coalescence and breakup; growth of cloud drops by collision and coalescence;

microphysics of ice particle-drop interactions; the electrical state of the atmosphere and its effect on cloud microphysics. In addition, there is a series of useful, mathematically rigorous and sometimes novel appendixes, on more specialised topics.

A feature of this book is the consistent attempt to provide a critical appraisal of published work. In general, these analyses are penetrating and balanced. Another impressive aspect is the bibliography which contains about 2,000 papers, concerning research carried out up to 1978.

A disadvantage of the analytical, microphysical approach adopted by the authors is that although individual topics are critically examined a broader overview of the status of areas of cloud physics is not consistently presented.

The emphasis on the physics rather than the dynamics and raw data is a deliberate and defensible policy which, however, is not uniformly successful. For example, the important research leading us towards a solution of the problem of thunderstorm electrification has been in the field—the laboratory and theoretical studies on which the authors have concentrated attention are of secondary consequence. These limitations—if valid—are minor, however, and there is little doubt that this impressive book will be of central importance to cloud physicists and scientists working in related fields.

J. Latham

J. Latham is Professor of Physics at the University of Manchester Institute of Science and Technology, Manchester, UK.

Inorganic analysis

Vogel's Textbook of Quantitative Inorganic Analysis. Fourth edition. Revised by J. Bassett, R. C. Denney, G. H. Jeffery and J. Mendham. Pp.925. (Longman: London and New York, 1978.) £14.

This fourth edition of 'Vogel' by four members of the late Dr Vogel's staff is considerably different from the previous versions that served as the standard textbook of quantitative inorganic analysis for several generations of British chemists. It uses SI units throughout, but in line with the recommendations of the Analytical Division of IUPAC it retains the concept of 'the equivalent' and the 'normal' solution, where it is more convenient and less ambiguous so to do. This is sound common sense in an era that spans the old and the new systems of nomenclature, and it serves the needs of a wide range of chemists and of industrial and academic requirements. The authors are to be congratulated on their pragmatic approach which may, of course, be denigrated by the pundits on either side, but which is eminently sensible at the present time.

Inevitably the new edition shows signs of fairly drastic pruning in the area of classical gravimetric and titrimetric analysis in the sense that the number of alternative classical procedures has been considerably reduced. The methods that have been retained are generally, in the reviewer's opinion, those that are most useful both on a practical analytical basis and for the purpose of training the next generation of students how to undertake

the elements of classical analysis that are still much used in industry and are likely to be required for many years to come. The decision to expand the section on sampling procedures is doubly welcome as all too many textbooks ignore this vital function without which most analyses are virtually pointless.

A new chapter has been devoted to thermoanalytical procedures and the one on infrared analysis which featured in the third edition has been deleted. This has allowed considerable expansion in other areas of spectrochemistry, for example, atomic absorption and emission spectrography, and a new chapter has been added on gas chromatography. The new arrangement of the material in the section on electroanalytical chemistry is also a considerable improvement on the previous edition. There have also been some changes in the extremely useful appendixes that have always characterised Vogel, for example, the omission of 'chemical factors' and the little used five-figure logarithms, though the four-figure tables are still there to help the chemist with his pH calculations.

Taken all round Vogel is still an excellent book and, in this reviewer's opinion at least, the authors have got the balance right. It contains a very useful blend of the best of classical and neo-classical techniques with the basis of many modern instrumental techniques set out in a way that the student can assimilate readily and follow subsequently with the selected list of references and recommendations for more advanced or detailed reading. The balance between theoretical background and laboratory practice is probably much better than it was even in the previous editions. The book is neatly printed and set out, there are

many useful illustrations and not too many 'commercial' pictures and line diagrams. A mine of information? Yes, but also a very interesting and stimulating one for all who have the opportunity to quarry therein. Unquestionably this is one of the best books available in this area. I only wish the

publishers had had more faith in its success to reduce the price and thus allow a greater audience of students to expose themselves to having their own copy.

T. S. West

T. S. West is Director of the Macaulay Institute for Soil Research, Aberdeen, UK.

Condensed state helium

The Physics of Liquid and Solid Helium. Part II. Edited by K. H. Bennemann and J. B. Ketterson. Pp.750. (Wiley: New York and Chichester, UK, 1978.) £45.85.

THE helium atom probably comes closer than any other to the miniature "billiard ball" of classical kinetic theory. One might expect, therefore, that the physics of liquid and solid helium would be exceptionally simple and even—perhaps, rather dull. The reality is far otherwise, thanks mainly to the profound influence of quantum statistics: a collection of these small, rigid spheres displays a quite unparalleled richness and variety of physical phenomena some of which, such as bulk superfluidity, are unique on earth (although they may, perhaps, also manifest themselves within the nucleonic fluids in the interiors of dense stars).

In the 1960s it was still possible (just) for a single author to prepare a research monograph providing a reasonable coverage of virtually everything that was known about condensed state helium; but, such has been the expansion of knowledge over the intervening years, this is hardly the case any more in the late 1970s. The admirable texts by Wilks (*The Properties of Liquid and Solid Helium*; Clarendon: Oxford, 1967) and by Keller (*Helium-3 and Helium-4*; Plenum: New York, 1969) are thus almost certainly the last of their kind. In presenting the fruits of more recent researches, Bennemann and Ketterson have very sensibly chosen to solicit individual chapters from a selection of experts. Although inevitably lacking the coherence, internal self-consistency and the helpful cross-referencing associated with a single-author monograph, the result is a collection of weighty, authoritative and, on the whole, very interesting review articles.

This second volume is strongly biased towards helium-3 which is, of course, entirely appropriate given the enormous progress made towards elucidating the properties of its super-

fluid phases following their discovery in 1972. The first three chapters are tough going, relatively speaking, being mostly devoted to a formal development of the theory: Baym and Pethick deal with the theory of normal (non-superfluid) liquid ^3He and with ^3He - ^4He solutions; Anderson and Brinkman cover anisotropic superfluidity in liquid ^3He . Most graduate students would be well advised to start instead on chapter 4, by Lee and Richardson. Running to more than 200 pages their contribution is virtually a book in its own right. They explain and discuss in considerable detail almost all the experimental work carried out on superfluid ^3He up to a cut-off date in mid 1976, conveying in an admirable way the relationship between the experiments

and the growing theoretical structure.

The remaining chapters are devoted to articles on three very disparate topics: by Dash and Schick on two-dimensional helium, concentrating, in particular, on the recent fascinating investigations of helium adsorbed on grafoil substrates; by Brewer on multilayer helium films in restricted geometries; and by Price on neutron scattering from helium. Each of these is excellent in its own way and, like the articles on ^3He , they should be a real help both to people entering, as well as to those already working in, the field in question.

The quality of production is high, as indeed it should be, considering the price. Very few private individuals will be able to afford personal copies; but the book provides a substantial and probably lasting contribution to the literature on condensed state helium and, as such, it will obviously be an essential purchase for libraries.

P. V. E. McClintock

P. V. E. McClintock is Senior Lecturer in the Department of Physics at the University of Lancaster, UK.

Bile salts

The Biological Importance of Bile Salts. By G. A. D. Haslewood. Pp.206. (North-Holland: Amsterdam, New York and Oxford, 1978.) \$55.75; Dfl.125.

THE interest in bile salts of the author of this useful publication is of very long standing. However, the author points out in the preface that this volume does not represent a second edition of his earlier publication entitled *Bile Salts* (1967). As remarked later in the present book, its purpose is to put the reader into the biological picture (physiological, biochemical, taxonomic and medical) regarding bile salts.

How can such a slim volume, with only some 200 pages, expect to achieve this aim? Professor Haslewood has succeeded by being selective. The book does not, for example, deal in any detail with the chemistry of bile salts, and the references (up to 1978) are described as a personal choice selected partly for their general interest. The author considers that, in these times of computer storage and retrieval, completeness seems an unnecessary aim and may make reading difficult and dull. Several chapters therefore commence by providing appropriate documentation to comprehensive earlier sources for background information.

The monograph has been produced to a high standard, with few printer's errors. It has five main chapters, of which the longest reflects the author's interest in the distribution of bile salts in the animal kingdom—for example, "Thus, crocodilian bile is quite primitive and generalised: a halt on the main route of bile salt evolution". The other chapters deal with the nature and function of bile, chemistry and methods of separation and analysis of bile salts, their biosynthesis and artefacts of the enterohepatic circulation, and their medical importance.

An Appendix contains 16 pages of tabulated data consistent with the intention that, throughout their studies, the author and his colleagues have tried to publish records of all bile salts discovered. The possible medical relevance of such compilations is shown by the observation (p189) that the tree "shrew" has advantages as a laboratory animal since this primate has bile much more like man than other small laboratory species, and can easily be induced to form cholesterol gallstones.

This monograph will thus be useful to many workers concerned with a number of different aspects of bile salts in biology and medicine.

announcements

Meetings

9–10 April, **Enzyme Inhibitors as Drugs**, London (Mrs J. Kruger, Dept of Pharmacology, School of Pharmacy, Brunswick Square, London WC1).

11 April, **Computers in Drug Research and Development**, London (Society for Drug Research, c/o Institute of Biology, 41 Queen's Gate, London SW7, UK).

17–18 April, **1st European Conference on the Protection of Farm Animals**, Amsterdam (Barban Public Relations Ltd, 43 Great Marlborough Street, London, W1, UK).

18–19 April, **The Terrestrial Environment and the Origin of Land Vertebrates**, Newcastle upon Tyne (Dr A. L. Panchen, Dept of Zoology, The University, Newcastle upon Tyne, UK).

23–24 April, **Stereodynamics of Molecular Systems**, New York (Dr R. H. Sarma, State University of New York at Albany, 1400 Washington Avenue, Albany, New York 1222).

29 April–2 May, **Ceramic Quality, Durability and Reliability**, Cincinnati (American Ceramic Society, 65 Ceramic Drive, Columbus, Ohio 43214).

10 May, **Safety in Research Laboratories**, London (The Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1, UK).

22–25 May, **13th International Leuko-**

cyte Culture Conference, Ottawa (K. Charbonneau, c/o National Research Council of Canada, Ottawa, Canada KIA OR6).

10–30 June, **The Transformed Cell**, New York (Cold Spring Harbor Laboratory, New York 11724).

10–30 June, **Advanced Bacterial Genetics**, New York (Cold Spring Harbor Laboratory, New York 11724).

21–22 June, **Lysosomes in Endocrine Secretion**, Marseille (Prof. C. Simon, Laboratoire d'Endocrinologie Cellulaire, Université de Provence, Centre St-Charles, 3 Place Victor Hugo, 13331 Marseille Cedex 3, France).

25–27 June, **Amino Acid Analysis in Clinical Chemistry and Medical Research**, Edinburgh (Dr J. M. Rattenbury, Dept of Paediatric Biochemistry, Royal Hospital for Sick Children, Edinburgh, UK).

27–29 June, **2nd International Conference on Lubrication Challenges in Metal-Working and Processing**, Illinois (IIT Research Institute, 10 West 35 Street, Chicago, Illinois 60616).

27–29 June, **Implantable Transducers and Systems: Packaging Methods and Testing Criteria**, Stanford (Prof. J. B. Angell, Electrical Engineering Dept, Stanford University, California 94305).

3–23 July, **RNA-TV**, New York (Cold Spring Harbor Laboratory, New York 11724).

3–23 July, **Molecular Biology and Developmental Genetics of Drosophila**, New York (Cold Spring Harbor Laboratory, New York 11724).

25 June–7 July, **Medical Physics**, Varenne (Prof. M. Della Corte, Istituto di Fisica Medica e Medicina Nucleare, Viale Morgagni, 85, 50134 Firenze, Italy).

9–21 July, **Nuclear Structure and Heavy Ion Collisions**, Varenna (Prof. R. A. Ricci, Istituto di Fisica Galileo Galilei, Università di Padova, Via Marzola, 8, 35100 Padova, Italy).

23 July–4 August, **Physics of the Earth's Interior**, Varenna (Prof. E. Boschi, Istituto di Geofisica dell'Università, Via Irnerio, 46, 40126 Bologna, Italy).

25 July–14 August, **Yeast Genetics**, New York (Cold Spring Harbor Laboratory, New York 11724).

30 July–12 August, **Immunogenetics**, New York (Cold Spring Harbor Laboratory, New York 11724).

13–16 August, **Impact of Intensive Harvesting on Forest Nutrient Recycling**, Syracuse (Dr A. L. Leaf, SUNY College of Environmental Science and Forestry, Syracuse, New York 13210).

24–30 August, **The Ammonoidea**, York (Dr J. R. Senior, Dept of Extra-Mural Studies, 32 Old Elvet, Durham, UK).

Gordon Research Conferences; Frontier of Science; 1979 Schedule—New Hampshire

	Colby-Sawyer College New London, NH	New Hampton School New Hampton, NH	Kimball Union Academy Meriden, N.H.	Tilton School Tilton, NH	Proctor Academy Andover, NH	Holderness School Plymouth, NH	Brewster Academy Wolfeboro, NH	Plymouth State College Plymouth, NH
11–15 June	*Elastin	Nucleic Acids	Cyclic Nucleotides	Theoretical Biology and Biomathematics	Free Radical Reactions	Physical Organic Chemistry (Hydrocarbon Chemistry)	Space Plasma Physics	*Red Cells
18–22 June	Nuclear Chemistry	Environmental Sciences: Air Proteins	Lipid Metabolism	Animal Cells and Viruses	Plant Cell and Tissue Culture	Mammary Gland Biology	Magnetic Resonance Atomic Physics	Calcium Phosphates
25–29 June	Catalysis		Atherosclerosis	Carbohydrates, Chemistry of Polymer Colloids	Polyamines	Biological Regulatory Mechanisms		Molecular Pharmacology
2–6 July	Fiber Science	Bacterial Cell Surfaces	Interfaces, Chemistry at Bones and Teeth, Chemistry, Physiology and Structure of Enzymes, Coenzymes and Metabolic Pathways	Nuclear Structure Physics	Cell Adhesion and Movement	*Analytical Pyrolysis	Nonlinear Optics	Fuel Science
9–13 July	Polymers	Heterocyclic Compounds, Chemistry of	Point and Line Defects in Semiconductors		Physical Metallurgy	Solids, Chemistry and Physics of	Molecular Pathology	Quantum Solids and Fluids, Dynamics of
16–20 July	Elastomers	Organic Reactions and Processes	Safety Evaluations	Biomaterials, Science and Technology of	Energy Coupling Mechanisms	Chemotherapy of Experimental and Clinical Cancer	Macromolecules and Behavior	Quantitative Structure Analysis
23–27 July	Corrosion	Natural Products		*Food Microbiology	Organic Photochemistry	Drug Metabolism	Microbiological Degradation	Tumor Immunology
30–3 August	Food and Nutrition	Statistics in Chemistry and Chemical Engineering	Toxicology and Safety Evaluations	Muscle Ionic Channels in, and Other Excitable Membranes	Developmental Biology	Fertilization and the Activation of Development	Ceramics, Solid State Studies in	*Ion Containing Polymers
6–10 August	Medicinal Chemistry	Inorganic Chemistry	Glycoproteins and Glycolipids	*Epithelial Differentiation and Keratinization	Coatings and Films, Chemistry and Physics of Catecholamines	Postharvest Physiology	Micellar and Macromolecular Catalysis	Magnesium in Biochemical Processes
13–17 August	Separation and Purification	Analytical Chemistry	Fluids in Permeable Media	Laser Interaction with Matter		Liquids, Chemistry and Physics of Inorganic Geochemistry	Few Body Problems in Chemistry and Physics	*Dynamics of Gas-Surface Interactions
20–24 August	Cancer	Adhesion, Science of	Ion Exchange	Transport Phenomena in Lipid Bilayer and Biological Membranes	Elementary Particle Interactions		Molten Salts and Metals	*Remote Sensing of the Earth's Surface from Space

Reports and Publications

UK and Ireland—February

- Countryside Commission. New Long Distance Path Leaflets. Offa's Dyke Path. The Cleveland Way. Pembrokeshire Coast Path. The Penine Way. North Downs Way. South Downs Way. South Devon Coast Path. The Ridgeway Path. Cornwall Coast Path. Dorset Coast Path. Somerset and North Devon Coast Path. (Cheltenham, Gloucestershire: The Countryside Commission, John Dower House, Crescent Place, 1979.) **gratis.** [12]
- Nutrition in Eye Health and Disease. By Stanley C. Evans. Pp. 38. (London: Roberts Publications, 225 Putney Bridge Road, SW15, 1978.) £1.50. [12]
- The Association of Commonwealth Universities. Annual Report of the Council 1977-78. Pp. 50. (London: The Association of Commonwealth Universities, 36 Gordon Square, WC1, 1979.) [12]
- United Kingdom of Great Britain and Northern Ireland. Report on the Implementation of the Convention on International Trade in Endangered Species of Wild Fauna and Flora in the United Kingdom, 1 January-31 December 1977. Pp. 74. (London: Department of the Environment, 2 Marsham Street, SW1, 1979. Available from Department of the Environment, Wildlife Conservation Licensing Section, Tollgate House, Houlton Street, Bristol.) [12]
- Ministry of Overseas Development. Report on Research and Development. 1978. Pp. 76. (London: HMSO, 1978.) £2 net. [22]
- Health and Safety Executive. Health and Safety Statistics, 1976. Pp. vi+65. (London: HMSO, 1979.) £1.75 net. [22]
- Tropical Products Institute. Grain Processing Losses Bibliography: Covering Threshing, Shelling, Hulling, Milling, Grinding etc. and Excluding Harvesting and Storage. By Ruth Kasasian and D. A. V. Dendy. Pp. iv+47. (G117). (London: Tropical Products Institute, 56/62 Gray's Inn Road, WC1, 1979.) £1.35. [22]
- The Glasshouse Crops Research Institute. Annual Report, 1977. Pp. 226. (Rustington, Littlehampton, West Sussex: The Glasshouse Crops Research Institute, 1978.) [52]
- The Universities Central Council on Admissions. Sixteenth Report, 1978-77. Pp. 28. (Cheltenham, Glos.: The Universities Central Council on Admissions, 1979.) 65p. [52]
- The Hannah Research Institute. (University of Glasgow). Report 1978. Pp. 126. (Ayr, Scotland: The Hannah Research Institute, 1979.) £2.50. [72]
- Health and Safety Executive. Packaging and Labelling of Dangerous Substances: Regulations and Guidance Notes. Pp. iii+23. (London: HMSO, 1978.) 60p plus postage. [82]
- Health and Safety Executive. Safety in the Use of Timber Pallets. (Guidance Note PM 15.) Pp. 8. (London: HMSO, 1979.) 30p plus postage. [82]
- Department of the Environment: Central Unit on Environmental Pollution. Pollution Control in Great Britain: How It Works. (Pollution Paper No. 91) Pp. vi+107. (London: HMSO, 1978.) £2.25 net. [92]
- The Supply of Potential Technicians, Craftsmen and Operators from the Education System to the Engineering Industry. By T. Fiddett. Pp. 84. (RP/3/78). (Watford: Engineering Industry Training Board, 54 Clarendon Road, 1978.) [92]
- An Introductory Guide to Information Sources in Physics. By L. R. A. Melton. Pp. 44. (Bristol and London: The Institute of Physics, 1978.) £1.25. [122]
- Advisory Council for Applied Research and Development. Industrial Innovation. Pp. 43. (London: HMSO, 1978.) £1 net. [121]
- Health and Safety Commission. Proposal to Amend the Agriculture (Tractor Cabs) Regulations, 1974, to Align with EEC Special Directives on Noise Requirement and Roll Over Protection Structures (Safety Cabs). (Consultative Document). Pp. 7. (London: HMSO, 1979.) 20p net. [122]
- Report of The Rugby School Natural History Society for the year 1977-78. (One Hundred and Eleventh Issue). Pp. 44. (Rugby: The Rugby School Natural History Society, 1979.) [122]
- Philosophical Transactions of the Royal Society of London. A: Mathematical and Physical Sciences. Vol. 290. No. 1376: Pathways of Pollutants in the Atmosphere. A Discussion organized by T. M. Sugden, F.R.S., for the Royal Society's Study Group on Pollution in the Atmosphere. Pp. 467-637 + 1 plate (London: The Royal Society, 1979.) UK £11.20; Overseas £11.70. [122]
- Medical Teacher, Vol. 1, No. 1, January/February 1979. Published bi-monthly. Pp. 1-56. Subscription: £13; \$32. (London: Update Publications, Ltd., Alfred Place, WC1; Fort Lee, New Jersey: Update Publishing International, Inc., 2337 Lemoine Avenue, 1979.) [132]
- Life and Death Before Birth: a Study of the Human Problems Arising from the Use of Antenatal Diagnostic Techniques. Pp. 64. (London: Council for Science and Society, 3/4 St. Andrews Hill, 1979.) £1.50. [132]
- Natural Environment Research Council: Institute of Terrestrial Ecology. Biological Records Centre. By John Heath and Franklyn Perring. Pp. 20. (Huntingdon: Institute of Terrestrial Ecology, Monks Wood Experimental Station, 1978.) 80p net. [162]
- Philosophical Transactions of the Royal Society of London. B: Biological Sciences. Vol. 285, No. 1005: The Primitive Cynodont *Procyonotuchus*: Functional Anatomy of the Skull and Relationships. By T. S. Kemp. Pp. 73-122 + plates 1-3. (London: The Royal Society, 1979.) UK £4.28; Overseas £4.50. [192]
- Geological Survey of Northern Ireland. Department of Commerce. Geology of the Causeway Coast. By

- H. E. Wilson and P. I. Manning. (Memoir for One-Inch Geological Sheet, 7.) Vol. 1: Pp. X+1-72 + plates 1-23. £2.95 net. Vol. 2: Pp. vii+73-172 + plates. 24-37. £13 net. (Belfast: HMSO, 1978.) [192]
- National Radiological Protection Board. NRPB-R73; The Influence of the Physico-Chemical Form of the Aerosol on the Radiological Consequences of Notional Accidental Releases of Radioactivity from a Fast Breeder Reactor. By G. N. Kelly, J. A. Jones and J. R. Simmonds. Pp. iv+145. (Harwell, Didcot: National Radiological Protection Board, 1979. Obtainable from HMSO.) £3. [192]
- The Parliamentary and Scientific Committee. Annual Report 1978. Pp. 24. (London: Secretary, The Parliamentary and Scientific Committee, 30 Farringdon Street, EC4, 1979.) £1. [202]
- Countryside Commission. Countryside Bill 1978: Comments by the Countryside Commission. Pp. 12. (Cheltenham, Glos.: Countryside Commission, John Dower House, Crescent Place, 1979.) **gratis.** [202]
- Ministry of Agriculture, Fisheries and Food. Report of the Director of Fisheries Research, 1974-77. Pp. 80. (Lowestoft, Suffolk: Ministry of Agriculture, Fisheries and Food, Directorate of Fisheries Research, 1978.) [202]
- Third Report of the Advisory Board for the Research Councils, 1976-1978. Pp. vii+27. (Cmd. 7467). (London: HMSO, 1979.) 70p net. [212]
- Professional Ideals and Planning Practice. By Patsy Healey and Jacky Underwood. Pp. 73-127. (*Progress in Planning*, Vol. 9, Part 2.) £4. An Analysis of New Industry Location—The Irish Case. By P. N. O'Farrell. Pp. 139-229. (*Progress in Planning*, Vol. 9 Part 3.) £4. (Oxford and New York: Pergamon Press, 1978.) [212]
- Scarce Resources in Health Care. Pp. 24. (London: Office of Health Economics, 162 Regent Street, W1, 1979.) 35p. [222]
- Philosophical Transactions of the Royal Society of London. A: Mathematical and Physical Sciences. Vol. 290. No. 1377: Nonlinear Wave Packets in the Kelvin-Helmholtz Instability. By M. A. Weissman. Pp. 639-685. (London: The Royal Society, 1979.) UK £2.38; Overseas £2.58. [222]
- Compare Your Home Heating Costs. (An Independent Guide to the Costs of Different Fuels and Heating Methods and How to Reduce Them.) Pp. 17. (London: Library of Energy, Thames House South, Millbank, SW1, 1979.) **gratis.** [222]
- Waste Management Advisory Council: Waste as Fuel Working Party. Energy from Waste. Pp. 47. (London: HMSO, 1979.) £1.50 net. [232]
- Enzyme and Microbial Technology*, Vol. 1, No. 1, January 1979. Managing Editor: Christopher J. Rawlins. Assistant Editor: Monique Heald. Published quarterly. Pp. 1-72. Annual subscription, including postage by surface mail: £40 UK and overseas. Single copies: £10. (Haywards Heath, Sussex: IPC (Sales and Distribution), Ltd., Oakfield House, Perrymount Road, 1979.) [262]

newly on the market

Laboratory timer. Nuclear Enterprises. The laboratory timer 2546, designed by Nuclear Enterprises, measures accurately to 1,000th of a second, and is ideal for radiation dosimetry and for general laboratory timing. The pocket sized, battery operated timer provides accurate measurements of elapsed time and incorporates two ranges of 999.999 s and 9999.99 s. These are displayed digitally on a liquid crystal, 7-segment element display.

Circle No. 51 on Reader Enquiry Card.

Nuclear Enterprises laboratory timer

Ultra-fine temperature probe. Bailey. An implantable temperature-sensing microprobe, believed to be the smallest of its type ever made, is announced by Bailey Instruments. Type IT-21 is a 12-inch Teflon tube with an o.d. of 0.013 ins having a microthermocouple in the sealed tip and terminating in a miniature copper/constantan type T plug, for connection to any Bailey BAT thermometer.

Circle No. 52 on Reader Enquiry Card.

CO₂ Incubators. Burkard. A new CO₂ incubator range, the Lab-Line Imperial 111 Modular CO₂ incubators, with complete system control, is available from Burkard Scientific. Features include the use of digital set points for temperature and CO₂ and a calibrated set point for relative humidity. Humidity, CO₂ level and temperature are readable at all times by direct digital LED readout. A new feedback system, with a two stage output for fast recovery to set chamber conditions, keeps CO₂ consumption to a minimum.

Circle No. 53 on Reader Enquiry Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the cover.

Fluorescence detection micro flow cells. Perkin-Elmer. A new rectangular liquid chromatography micro flow cell for fluorescence detection from Perkin-Elmer offers a signal-to-noise value 4.5 times better than that obtained with cylindrical cells. Two models have been introduced: one for use with the Company's line of MPF instruments and the other for use with model 204 fluorescence spectrophotometer. Measured signal-to-noise values of the new 20 μ l cell approach values obtained with standard 3 ml cells.

Circle No. 54 on Reader Enquiry Card.

Gel filtration medium. Pharmacia. Pharmacia Fine Chemicals present a new high performance medium, Sephacryl S-300 Superfine, for gel filtration of proteins, polysaccharides and other biopolymers. This medium provides excellent resolution over an unusually wide fractionation range, exclusion limit for globular proteins approximately 2 million, making it ideal as a general purpose gel filtration medium. As well as good separation characteristics, Sephacryl S-300 Superfine has good flow properties. For separations where all the components of interest are smaller than about 250,000 (globular proteins), Sephacryl S-200 Superfine is recommended. Sephacryl S-300 Superfine and Sephacryl S-200 Superfine are available in packs containing 750 ml pre-swollen gel.

Circle No. 55 on Reader Enquiry Card.

Microchopper. Rofin. The micro-chopper from Rofin is designed to fit into the smallest spaces, into OEM applications and into experiments. It measures only 31 mm diameter and is frequency programmable over the range 50–2,000 Hz, or 10–500 Hz. The unit features a digital LED readout, and has a printed circuit board built in behind the chopping wheel which enables the user to plug in a TO5 or similarly sized detector.

Circle No. 56 on Reader Enquiry Card.

Silicon avalanche photodiode. Coherent. The Coherent picosecond diode, consists of the fastest avalanche photodiodes commercially available together with a precision 50 Ω coaxial assembly. The picosecond diode may be used wherever general high speed research work is undertaken. It requires neither precision mounting nor focusing optics.

Circle No. 57 on Reader Enquiry Card.

Dispensing pipette. Brand. A selection of micro litre dispensing pipettes by Brand are now available. Use of disposable tips with the pipettes enables volumes in the range 5–1,000 μ l to be dispensed accurately and efficiently. Called the transferpette, it has an overall length of 270 mm, and is operated by pressing a button on the top of the pipettor body. An insulating jacket minimises any effect created by hand heat and a PTFE sleeve and flexible O-ring provide positive internal sealing in the transferpette.

Circle No. 58 on Reader Enquiry Card.

Laboratory computer system. Digital. Designated DEClab-11/MNC, the new Digital laboratory computer system uses twin R101 disk storage units for a standard 10-megabyte capacity and its fundamental programming is done in ANSI-standard FORTRAN IV, supplemented with Digital-supplied subroutine packages. The new system is housed in a 41-inch (104 cm) high cabinet. The DEClab-11/MNC system design permits the use of the system's configuration through use of plug-in 'MNC modules.'

Circle No. 59 on Reader Enquiry Card.

Pye Unicam HPLC aid.

HPLC Aid. Pye Unicam have launched a new addition to their LC-XP range of high performance liquid chromatography instruments. Known as LC-XP Dialamix, this unit delivers any desired isocratic mixture of two solvents to the inlet of a reciprocating pump. With its integral degassing facilities and highly efficient dynamic mixing system, the unit provides a significant time saving compared with traditional hand-mixing techniques. The desired solvent composition is rapidly selected by means of a digital front panel switch which initiates mixing in the three-port PTFE solenoid valve and magnetically stirred chamber.

APPOINTMENTS VACANT

LECTURESHIP IN GEOGRAPHY

Applications are invited for the post of Lecturer in Geography. Candidates should have a specialist interest in Geomorphology and preference may be given to those with research interests in Pleistocene studies.

Salary Scale: £4317-£8487. Appointment is likely to be made in the range £4317-£5235. There is a non-contributory pension scheme.

Interested persons should, in the first instance, telephone the Staff Office, Trinity College, on Dublin 772941 Ext. 1678/1775.

The closing date for receipt of applications will be 17th April 1979.

W6(A)

UNIVERSITY OF BIRMINGHAM DEPARTMENT OF GEOGRAPHY LECTURESHIPS IN GEOGRAPHY

Applications are invited for two posts. 1) Lecturer in hydrology or meteorology. Preference may be given to candidates who can demonstrate competence in both fields.

2) Lecturer in the geographical aspects of planning. Preference may be given to candidates with special interests in industry or resource management.

Salary will be in the range £3,883 to £7,754 (under review) plus superannuation. Maximum starting salary will be according to age, experience and qualifications, but appointment will be towards the lower end of the scale.

Further particulars are available from the Assistant Registrar, Science and Engineering, University of Birmingham, P.O. Box 363, Birmingham B15 2TT, to whom applications (3 copies) including full curriculum vitae and naming 3 referees, should be sent by Thursday April 19, 1979.

Please quote ref: NHS. 156(A)

IMPERIAL COLLEGE LONDON TWO BIOCHEMISTS/ NEUROCHEMISTS

Two Scientific Research Assistants with two or three years post-doctoral research experience are required for M.R.C.-funded projects on cellular biochemical aspects of the organisation and function of neurotransmitter systems at synapses in the mammalian C.N.S.

For one post a background in neurochemistry is not a strict requirement, but experience with incubating tissues, subcellular fractionation, affinity chromatography, ligand-binding assays, or protein chemistry would be advantageous.

The second post is for a neurochemist/neuropharmacologist with experience in catecholamine or indoleamine transmitter systems. The successful candidates would join a team of ten working on closely related topics.

One post is available from April 1 and would be renewable on an annual basis for at least five years, the second will be available on October 1.

Salary would be commensurate with experience. Applicants should send curriculum vitae and the names of two referees to Dr. H. F. Bradford, Department of Biochemistry, Imperial College, London SW7 2AZ. 150(A)

EDINBURGH & S.E. SCOTLAND REGIONAL BLOOD TRANSFUSION SERVICE Royal Infirmary, Edinburgh POSTDOCTORAL RESEARCH FELLOW OR GRADUATE RESEARCH ASSISTANT

Required to undertake a project which involves the development of procedures for isolating, purifying and characterising red cell antigens, and the use of purified antigens for the production of antisera. The work will be carried out in a laboratory producing a range of immunological reagents, and will involve collaboration with other laboratory staff in evaluation of antisera as potential red cell typing reagents. Applicants should possess an Honours B.Sc. or a Ph.D. in Biochemistry or a related discipline.

The post is for three years. Salary range £3,486 to £3,798, N.H.S. Whitley Council conditions of service apply. Starting date by arrangement.

Applications to and further details from Dr. D. B. L. McClelland, Regional Transfusion Centre, Royal Infirmary, Edinburgh. Tel: 031-77291, by April 16, 1979. 123(A)

FACULTY POSITION IN INSECT PATHOLOGY DEPARTMENT OF ENTOMOLOGICAL SCIENCES, COLLEGE OF NATURAL RESOURCES UNIVERSITY OF CALIFORNIA Berkeley

Full-time, 11-month research (75%) and teaching (25%) position available in insect pathology at the Assistant Professor level available July 1, 1979. Expertise mandatory in one of the following areas: bacteriology, comparative virology, mycology, or protozoology. Ph.D. and background in pathology required and postdoctoral experience desirable.

Responsibilities will be in basic and applied research and teaching in insect pathology and pest management. Experience in pathogen-insect relationships, pathogenicity, and the manipulation of pathogens for insect control will be weighting factors when judging applicants.

Send full curriculum vitae, official transcripts, copies of significant publications or manuscripts, and names of three references by May 1, 1979 to Evert I. Schlinger, Acting Chairman, Department of Entomological Sciences, 137 Giannini Hall, University of California, Berkeley, California 94720. The University of California is an equal opportunity, affirmative action employer. W21(A)

EDINBURGH & S.E. SCOTLAND REGIONAL BLOOD TRANSFUSION SERVICE Royal Infirmary, Edinburgh RESEARCH ASSISTANT

Research assistant required for a three-year supervised project on the development of sensitive specific methods for detecting and quantitating immunoglobulin and complement bound to the human red cell. The work will involve the isolation of highly purified plasma proteins, production of antisera, and development of assay systems. Applicants should possess an honours degree or an equivalent qualification in Biochemistry or a related subject.

The post is available from April 1, 1979. Salary range £3,486 to £3,798, N.H.S. Whitley Council conditions of service apply.

Applications as soon as possible to Dr. D. B. L. McClelland, Regional Transfusion Centre, Royal Infirmary, Edinburgh, from whom further information may be obtained. 122(A)

WYE COLLEGE (University of London) LECTURER IN BIOCHEMISTRY

Applications are invited for the post of Lecturer in Biochemistry. The post is a permanent one. Candidates are expected to possess an honours degree in Biochemistry with a Ph.D. and post-doctoral research experience in some aspect of animal biochemistry. Experience in lipid biochemistry would be an advantage.

Applications to be forwarded to the Secretary, Wye College, Wye, Ashford, Kent TN25 5AH (from whom further particulars of the post may be obtained) by April 25, 1979 at the latest. 149(A)

DESIGNER (SCIENCE PROJECTS) OPEN UNIVERSITY PRODUCTIONS

Are you interested in the presentation of science through television? There is an opportunity to work on the design and preparation of scientific and technological experiments and demonstrations for Open University television programmes. Applicants must have mechanical workshop skills and should have experience of electronics to HNC level or equivalent. Ability to work in a wide range of scientific areas, e.g. Chemistry, Biology, Geology and Physics is essential.

Based at Alexandra Palace, North London, but it is anticipated that Open University Productions will move to Milton Keynes in 1981.

Salary (under review): £5,890 p.a. (may be higher if qualifications exceptional) by £225 to £7,015 p.a. Relocation expenses considered.

Telephone or write immediately for an application form, enclosing addressed envelope and quoting reference 2183/NA, to **Appointments Department, BBC, London W1A 1AA. Telephone: 01-580 4468, ext. 4619.**

168(A)

CELL BIOLOGIST/BIOCHEMIST. Ph.D. 1970. Teaching and research experience. Established research program and publications in areas of cardiac and skeletal muscle ultrastructure, muscle membrane ion transport. Extensive experience in conventional electron microscopy as well as freeze fracture. Desire position in U.K. Curriculum vitae and references gladly sent to serious inquiries. Reply to Box 5(B), c/o Nature, 3 Dyers Buildings, Holborn, London EC1N 2NR. W5(A)

**Chemical
Engineers
Metallurgical
Engineers
Instrument
Engineers
Analytical Chemists
Industrial
Chemists**

The National Institute for Metallurgy, which is one of the largest mineral-processing laboratories in the World, and which is situated on the northern outskirts of Johannesburg, is at present, as a result of its very considerable list of scientific and technological successes, together with the rapid growth of the mineral industry in South Africa, entering a major expansion phase. The Institute has advanced equipment and very modern laboratories, workshops, and pilot-plant facilities, located in a pleasant rural atmosphere within easy reach of the city. To cope with this expansion, the Institute is looking for research staff to work on projects covering a wide field in minerals and metals.

Applicants should be in possession of a research degree in chemical engineering, extractive metallurgy, instruments or electronic engineering, analytical chemistry, industrial or pure chemistry, material science, minerals processing, or a related field. Post-graduate experience will be a recommendation, but is not essential.

The low cost-of-living structure and attractive salaries, based on education and experience, coupled with challenging opportunities, are some of the attractions of employment at the Institute.

Appointments may also be made on contract for two or three years, after which time the Institute will pay return fares for the applicant and his family.

The field of research covers hydrometallurgy, pyrometallurgy, refractory metals, the use of computers, the design and operation of pilot plants, and the automation of processes and the application thereof to full-scale plants. It also includes mineralogy, the study of surface chemistry, electro-chemistry, the properties of solutions, analytical chemistry, and the development of specialized electronic instruments. The large and well-equipped workshop can handle precision engineering jobs and pilot plant construction in a wide variety of materials. A large proportion of the work of the Institute is done on a joint venture basis in close collaboration with industry.

Benefits include a pension scheme, medical aid, a housing-subsidy scheme, 5-day working week, generous leave privileges (in addition to normal vacation leave, the Institute closes for the period between Christmas and New Year), flexitime, subsidized cafeteria facilities, sports facilities such as squash, tennis, swimming, snooker, etc., and an annual leave bonus. There are possibilities for advanced studies at universities, with substantial bursaries from the Institute.

The Institute will pay the fares to South Africa of the applicant and his family, contribute to removal expenses and grant a settlement allowance under certain conditions.

Please apply giving full details of age, qualifications, experience, etc., to:
The Office of the Scientific Counsellor,
South African Embassy, Chichester House,
278 High Holborn, LONDON, WC1V 7HE.

National Institute for Metallurgy

KEEPER

Conservation & Technical Services
£10,560-£11,820

The Department of Conservation and Technical Services of the British Museum, Bloomsbury, is primarily concerned with the conservation of items from the Museum's collections and elsewhere, and with scientific research into new methods and materials for conservation. It provides advice on conservation matters in liaison with other institutions and organisations in this field both in the United Kingdom and abroad.

The Keeper's duties include the general administration of the Department, the initiation and direction of research into problems of conservation, and the organisation and development of the practical and academic training of conservation staff.

Candidates, normally aged 35-54, must be of high academic standing in a relevant scientific field, preferably chemistry,

physics, conservation or materials science, with considerable experience in an appropriate field of work; particular attention would be paid to conservation experience. They must also have successful experience of managing staff and of initiating and directing research. Relevant contacts with international specialists in conservation are desirable.

Salary (under review) in the range shown above; non-contributory pension scheme.

For further details and an application form (to be returned by 17 April 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours).

Please quote ref: S/5091/79/3.

102(A)

UNIVERSITY OF EAST
ANGLIA
NORWICH

CHAIR IN DEVELOPMENT
STUDIES
(NATURAL RESOURCES)

Applications are invited for the Chair in Development Studies (Natural Resources) in the School of Development Studies. Candidates should have a particular interest in ecological and agricultural aspects of natural resource development, but other specialisations will not be excluded from consideration if there is evidence of concern with the wider implications of resource assessment, use, planning and management.

Candidates should be prepared to play a leading role in evolving programmes of teaching and research within an interdisciplinary framework, while also having a strong command of their own discipline and being concerned with practical solutions to development problems. The person appointed will be a member of the Overseas Development Group organised by the School, and will normally spend up to one-third of his or her time on outside financed assignments, usually overseas. Practical experience of operational or advisory work for government or international organisations will be useful.

Appointment will be at an appropriate point on the Professorial scale £9,443 to £11,532 (under review) plus U.S.S. benefits and will be tenable from October 1, 1979, or as soon as possible thereafter.

Applications (one copy only) giving the names of three persons to whom reference may be made, should be lodged with the Registrar and Secretary, University of East Anglia, Norwich NR4 7TJ (telephone 0603 56161, extension 2215) from whom further particulars may be obtained, not later than April 27, 1979. No forms of application are issued. In naming three referees you are particularly requested to give only the names of those who can immediately be approached. 165(A)

LEICESTER UNIVERSITY

CHAIR OF PHYSICS

Applications are invited for an additional Chair of Physics tenable from 1st October 1979 or an agreed later date. Candidates should be experienced in some branch of experimental physics.

Further particulars from the Registrar to whom applications should be sent by 21st April 1979. Candidates in the U.K. should submit 15 copies of their application (overseas candidates may submit one copy).

157(A)

UNIVERSITY OF
THE WITWATERSRAND,
Johannesburg, South Africa
DEPARTMENT OF
GENERAL PHYSIOLOGY
SENIOR LECTURER/
LECTURER

Applications are invited from persons suitably qualified in the medical, dental, veterinary or basic sciences, for appointment to the above post on the staff of the Department of General Physiology in the Faculty of Dentistry.

Senior Lecturer: Candidates should have a higher scientific, dental, veterinary or medical qualification, or have considerable teaching experience. Salary range attached to the post is R12,474 to R14,700 per annum.

Lecturer: Salary range for this post is R7,278 to R13,515 per annum.

The initial salary and level of appointment will be determined according to the qualifications and experience of the successful applicant. Duties to be assumed as soon as possible.

The University's policy is not to discriminate in the appointment of staff or the selection of students on the grounds of sex, race, religion or colour. Further particulars relating to this practice and the the above post are included in an information sheet obtainable from the London Representative, University of the Witwatersrand, Chichester House, 278 High Holborn, London WC1V 7HE, or from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, 2001 South Africa, to whom applications should be lodged by April 12, 1979. 129(A)

UNIVERSITY OF
ADELAIDE
CHAIR OF
CLINICAL PHARMACOLOGY

Applications are invited from qualified persons with teaching and research interests in Clinical Pharmacology who have a medical degree registrable in South Australia.

The new Professor will be invited to accept Chairmanship of a new Department of Clinical and Experimental Pharmacology formed from within the existing Department of Human Physiology and Pharmacology.

Present salary: \$A33,061 a year with provision for superannuation. In addition to the basic salary the Professor will receive, on account of his registrable medical qualification, a clinical loading at the rate of \$A5,000 per annum.

Further information, including the Formal Terms and Conditions of Appointment, the provisions of Departmental Government and details required in an application, is available from the Registrar of the University or from the Secretary General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF; further information about responsibilities, facilities, research interests in the Department, etc., may be sought from the Dean of the Faculty of Medicine, in the University.

Applications, in duplicate, giving the particulars listed in paragraph 10 of the statement should reach the Registrar of the University, G.P.O. Box 498, Adelaide, South Australia, 5001, not later than June 15, 1979. 100(A)

Chemical/ Metallurgical/ Instruments/ Mineral and Processing/ Technologists

The National Institute for Metallurgy, which is one of the largest mineral-processing laboratories in the World, and which is situated on the northern outskirts of Johannesburg, is at present, as a result of its very considerable list of scientific and technological successes, together with the rapid growth of the mineral industry in South Africa, entering a major expansion phase. The Institute has advanced equipment and very modern laboratories, workshops, and pilot-plant facilities, located in a pleasant rural atmosphere within easy reach of the city. To cope with this expansion, the Institute is looking for research staff to work on projects covering a wide field in minerals and metals.

Applicants should preferably hold a diploma in mineral processing, metallurgy, chemical

technology, measurement and control, or instrumentation.

Persons not holding such a diploma, but with considerable experience in any of these fields, are also welcome to apply.

The low cost-of-living structure and attractive salaries, based on education and experience, coupled with challenging opportunities, are some of the attractions of employment at the Institute.

Appointments may also be made on contract, for two or three years, after which the Institute will pay return fares for the employee and his family.

Benefits include a pension scheme, medical aid, a housing-subsidy scheme, 5-day working week, generous leave privileges (in addition to normal vacation leave, the Institute closes for the period between Christmas and New Year), flexitime, subsidized cafeteria facilities, sports facilities such as squash, tennis, swimming, snooker, etc., and an annual leave bonus. Post-Doctoral Organic Chemist

Miles Laboratories Ltd. are an international pharmaceutical company based in an attractive part of South Buckinghamshire.

We are currently seeking a Ph.D. level Organic Chemist to join a small synthetic team engaged in research into allergic diseases. Candidates should have 2-3 years post-doctoral experience, be capable of supervising graduate chemists, and will be expected to make a significant contribution to the Department's scientific programme. Preferred age 26-30.

In return we offer excellent conditions of employment, four weeks holidays, subsidised staff restaurant, free life and private health insurance, contributory pension scheme, flexible working hours.

For an application form please write or ring my secretary on Farnham Common 2151:

Mrs. Nancy Morgans
Personnel Manager
Miles Laboratories Limited
Stoke Court, Stoke Poges
SLOUGH. 107(A)

National Blood Transfusion Service (Wales)

SCIENTIFIC OFFICER

Salary: £2,991 to £4,275 per annum dependent upon qualifications.

A graduate in biological or natural sciences is required to assist in the investigation of platelet storage, testing and quality control. Work will involve the use of controlled rate cell freezing techniques, evaluation of platelet morphology and function and assessment of statistical data resulting from the use of platelet concentrates in the treatment of patients.

Applicants should preferably have experience in a relevant field and be prepared to take part in the normal research and development activities of the department. This appointment is on the basic grade Scientific Officer scale.

Terms and Conditions of Service.

All terms and conditions of service are in accordance with the Professional and Technical "A" Whitley Council and General Whitley Council for the Health Service.

Applications form and job description from: **National Blood Transfusion Service, Rhydlafar, St. Fagans, Cardiff. Tel: 0222 890302.**

Closing date: April 6, 1979.

COMMONWEALTH AGRICULTURAL BUREAU Vacancy for SCIENTIFIC INFORMATION OFFICER

at
NATIONAL INSTITUTE OF
AGRICULTURAL ENGINEERING
Wrest Park, Silsoe
Bedford MK45 4HS, U.K.

Duties of Post: The scrutiny of technical literature, selection and preparation of abstracts on all subjects related to agricultural and horticultural engineering (this may involve visits to outside libraries), indexing, proof-reading, and dealing with technical enquiries.

Qualifications: Applicants should have a knowledge of both engineering and foreign languages. They should have a degree or similar qualification in engineering or a relevant subject and a high competence in at least one foreign language, or a foreign language degree with a sound background knowledge of engineering. The ability to write clear concise English is essential.

Salary: In the scale £2,839 to £5,448, plus a compensatory allowance to offset personal contribution to superannuation. Starting salary according to qualifications and experience. Promotion to higher scales on merit.

Applications forms and full particulars from:

Executive Director,
Commonwealth Agricultural
Bureaux,
Farnham House,
Farnham Royal,
Slough SL2 3BN.

Closing date for applications: April 6, 1979. 138(A)

RESEARCH ASSOCIATE

Applications are invited for a possible appointment as research associate in theoretical astrophysical plasma physics, space plasma physics and/or cosmic-ray physics. The successful applicant will be expected to spend a substantial part of his or her time working on problems in solar or interplanetary physics.

Appointments will begin in Fall or Winter 1979. Applicants should possess a recently acquired Ph.D. in a relevant area of physics, astronomy, or planetary sciences.

Inquiries should be addressed to Prof. J. R. Jokipii or Prof. E. H. Levy, Department of Planetary Sciences, Lunar and Planetary Laboratory, University of Arizona, Tucson 85721.

Applications should be accompanied by resume, complete bibliography, and at least two letters of recommendation from persons who are well acquainted with the applicant's background and potential. All material should be received by June 1, 1979. An Equal Opportunity, Affirmative Action, Title IX, Section 504 Employer. W17(A)

THE UNIVERSITY COLLEGE OF WALES ABERYSTWYTH DEPARTMENT OF ZOOLOGY LECTURESHIP IN IMMUNOLOGY

Applications are invited for the above post which is tenable from October 1, 1979. It will be an advantage to have had a Biological training and to be able to take part in the teaching of vertebrate Biology.

Salary at the appropriate point within the range £3,883 to £7,754 per annum (under review).

Application forms and further particulars can be obtained from the Registrar, The University College of Wales, Old College, King Street, Aberystwyth, Dyfed, SY23 2AX, to whom completed forms should be returned no later than Friday, April 13, 1979. 112(A)

FACULTY POSITION AVAILABLE IN RETINAL HEMODYNAMICS AND BLOOD FLOW STUDIES

University of Illinois
Eye and Ear Infirmary
and
Abraham Lincoln School
of Medicine

The University of Illinois
at the

Medical Center, Chicago

Equal Opportunity/Affirmative
Action Employer

Applications are invited for a faculty position at the assistant or associate professor level. The major responsibility will be supervision of research of vascular flow in the retina, utilising a unique non-invasive computerised ophthalmoscopy system. Active interchange with engineers and clinical ophthalmologists will be fostered. An advanced degree (Ph.D. or M.D.) is a prerequisite.

Those interested should direct inquiries together with a curriculum vitae and bibliography to:

Morton F. Goldberg, M.D.
Professor and Head
Department of Ophthalmology
University of Illinois Eye and
Ear Infirmary
1855 West Taylor Street
Chicago, Illinois 60612

W2(A)

FACULTY POSITION IN NATURAL PRODUCTS CHEMISTRY

DEPARTMENT OF
ENTOMOLOGICAL SCIENCES
COLLEGE OF NATURAL
RESOURCES
UNIVERSITY OF
CALIFORNIA
Berkeley

Full-time, 11-month research (80%) and teaching (20%) position available in Natural Products Chemistry at the Assistant Professor level. Ph.D. in organic chemistry or other field(s) relevant to natural products required with evidence of interest in chemicals active in insects.

Responsibilities will be in basic and applied research involving bioactive chemicals from insects, plants, and other biological materials that influence insect growth, development, reproduction, and behaviour. Research will include identification and synthesis of active components, and studies of their potential use in managing insect populations. Teaching duties may include developing a course in chemical ecology, environmental chemistry, insect biochemistry, or chemical pest control.

Send full curriculum vitae, official transcripts, copies of significant publications or manuscripts, and names of at least three references by May 1, 1979 to Evert I. Schlinger, Acting Chairman, Department of Entomological Sciences, 137 Giannini Hall University of California, Berkeley California 94720. The University of California is an equal opportunity affirmative action employer. W20(A)

UNIVERSITY COLLEGE LONDON DEPARTMENT OF ANATOMY AND EMBRYOLOGY LECTURER/SENIOR LECTURER

An applicant is sought who is committed to any field of biomedical research. Facilities for research are outstanding.

Applications, including curriculum vitae and publications list to Assistant Secretary (Personnel), University College London, Gower Street, WC1E 6BT from whom further particular may be obtained. 179(A)

CSIRO

AUSTRALIA

Research Scientists

Centre for animal research
and development
Bogor, Indonesia

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees — 2,400 of whom are research and professional scientists — located in Divisions and Sections throughout Australia.

General: Australia is committed to assisting Indonesia in the establishment of an animal husbandry research laboratory and associated buildings, conducive to problem-solving research of the highest standard, with the long-term view of staffing it fully with Indonesian scientists trained to carry out first-class research. The agreement extends over a period of ten years and has been in operation for four years. The Australian aid contribution is administered by CSIRO on behalf of the Australian Development Assistance Bureau.

Modern well-equipped laboratories are nearing completion at Bogor 70 km from Jakarta. Excellent facilities are available for research on problems related to the nutrition, growth, reproduction, management, physiology and breeding of chickens, ducks, sheep, goats, cattle and buffaloes. In the longer term a field station is expected to provide additional opportunities for ruminant research, particularly with cattle and buffaloes.

The Centre is giving considerable emphasis to studying (a) factors that limit animal productivity at the village level, (b) problems of utilizing local byproducts in intensive poultry rations, (c) problems of management, feeding and breeding of ducks under intensive conditions, (d) the biology and production potential of Bali cattle in comparison with other breeds of cattle and with buffaloes, (e) the growth and reproductive potential of Indonesian sheep and goats, and (f) the problems associated with enhancing the use of local byproducts for ruminant rations generally. The Centre recognises the overriding importance of agricultural byproducts such as rice, bran, rice straw, cassava, animal faeces, etc. as the major source of livestock feedstuffs in Indonesia, and aims to develop special research expertise in the efficient utilization of these byproducts.

Research scientists at the Centre are supported by Veterinary and Analytical laboratories and other well-equipped supporting services such as library and workshop.

Vacancies exist for five senior scientists viz: Research Leader, Ruminant Nutritional Biochemist, Microbiologist, Research Chemist, and Biologist/Ecologist (Village Production Systems). These new appointees will join a group of 10-12 Australian and Indonesian scientists who are supported by technical staff. They will have major roles in the planning and development of long-term research policies and projects for the Centre. In addition to personal research, these scientists will participate in the continued training of Indonesian scientific and support staff. All applicants will be expected to have had experience in the management of research staff.

1. Research Leader

Duties: The Research Leader will be responsible to the Officer in Charge for the planning and management of the Centre's research programmes, the organization of seminars and the planning and guidance of training for young Indonesian scientists and technicians associated with the Centre.

Qualifications: PhD or equivalent qualifications, and international recognition for research in animal science. A broad background in animal science and a wide knowledge of Australian teaching and research centres and of animal scientists in Australia and overseas in order to provide a strong link between the Centre and animal scientists, particularly in Australia, but also internationally. An understanding of tropical livestock production as applied to a country like Indonesia. Experience in Staff Management.

2. Ruminant Nutritional Biochemist

Duties: To plan and conduct research aimed at developing village level technologies for overcoming nutritional limitations of Indonesian agricultural byproducts for ruminant feeding, giving initial consideration to the study of factors that limit the nutritional value of rice straw, rice bran and tree legumes. To investigate simple methods for storage of crops and byproducts as part of the development of village level technologies for enhanced ruminant production.

Qualifications: PhD or equivalent qualifications and extensive research experience in ruminant nutrition and/or biochemistry.

An interest in tropical plants and animals is essential. Experience in staff management.

3. Microbiologist

Duties: To plan and supervise fermentation studies aimed at enhancing the nutritional properties of agricultural byproducts, giving particular attention to the development of village level technologies appropriate for the production of microbial protein from these substrates. To undertake studies aimed at preventing the proliferation of mycotoxic fungi during storage of conventional feeds in Indonesia.

Qualifications: PhD or equivalent qualifications, with extensive experience in the microbiology of food or feeds or in the microbiology of waste product fermentations. Experience with mycotoxin-producing fungi desirable. An understanding and/or interest in tropical biology. Experience in staff management.

4. Research Chemist

Duties: To plan and supervise research aimed at overcoming the anti-nutritional and toxic factors such as alkaloids, tannins, mycotoxins, phytic acid, etc., which limit the nutritional value of Indonesian feedstuffs, and defining the mineral, amino acid and vitamin status of these feedstuffs. To collaborate with other scientists at the Centre to develop technologies to overcome these nutritional limitations.

Qualifications: PhD or equivalent qualifications, with extensive research experience in the field of Analytical Chemistry as applied to feeds, food or agriculture in general. A general understanding of the tropics and an interest in the problems of developing countries. Experience in staff management.

5. Biologist/Ecologist (Village Production Systems)

Animals in Indonesian villages are a vital part of a delicately balanced ecosystem which has been developed over centuries. With the increasing population and the consequent pressure on available land, demand for meat etc., it is necessary to introduce technologies which will help the village farmers in their efforts to maintain the balanced ecosystem.

Duties: To lead a research programme which will relate current research projects designed to increase livestock production to village livestock husbandry systems. In addition to the development of new findings, to consider the introduction or adaptation of proven technologies, breeds or feeds that already exist in other countries. To initiate and supervise research projects, and to work closely with research staff in other programmes at the Centre.

Qualifications: The position calls for someone with a deep interest and understanding of ecology, agricultural and animal husbandry as applied to villages in countries like Indonesia. The appointee will be expected to have appropriate academic qualifications (PhD or equivalent) and research experience in tropical biology or agriculture. Experience in the development of appropriate technologies in developing countries desirable. Experience in staff management.

Salary: Research Leader:

Principal Research Scientist/Senior Principal Research Scientist \$A23247 — \$A30530 p.a.

Other appointments:

Senior Research Scientist/Principal Research Scientist \$A19572 — \$A26368 p.a.

Appointment at higher levels will be considered for outstanding applicants for all positions.

Tenure: The period for which these positions is available is subject to negotiation, but a minimum of 3-4 years is envisaged. The appointee may be offered an indefinite appointment within CSIRO.

Applications in duplicate, stating full personal and professional details, the names and addresses of at least two professional referees, and quoting the reference number 1000/4S should reach: The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maltravers Street, LONDON WC2R 3EH, by 21st April 1979.

Applications in U.S.A. and Canada should be sent to: The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue N.W., WASHINGTON D.C. 20036

Carbohydrate Chemist

A vacancy exists for a carbohydrate chemist within the Biochemistry Department of The Lord Rank Research Centre at High Wycombe. The Biochemistry Department's activities particularly involve the biochemistry and chemistry of cereal crops and products.

Applications are invited from persons who are interested in basic research and in the structure and properties of natural polysaccharides and applications in the food and agriculture industries.

Applicants should have a strong background in carbohydrate research. A Ph.D. degree or equivalent research experience is a minimum requirement for this position and good career prospects exist for the person with the ability to lead others in a multi-disciplinary research environment. Publication of research work will be encouraged.

The Research Centre provides research and development facilities to the Ranks Hovis McDougall Group of Companies whose activities include the manufacture and distribution of a wide range of milling, baking, agricultural and convenience food products.

A competitive salary will be offered, dependent upon qualifications and experience, and the terms and conditions of employment are as expected of a major organisation. Please apply in writing with curriculum vitae, quoting reference CO1 to:

Personnel Administration,
RMH RESEARCH LIMITED,
The Lord Rank Research Centre,
Lincoln Road, High Wycombe, Bucks.

172(A)

LOTHIAN HEALTH BOARD SENIOR GRADE CYTOGENETICIST

Applications are invited from suitably qualified graduates for the above post, to be held in the Area Diagnostic Cytogenetics Laboratory, Royal Hospital for Sick Children, Edinburgh.

Experience in all branches of cytogenetics is essential, especially in relation to amniotic fluid cell analysis, tissue culture, and all types of banding techniques.

An interest in teaching could be helpful as the Department has a University teaching commitment.

Applications, which should be typewritten, giving particulars of age, qualifications and previous experience together with the names and addresses of two referees should be lodged with the Secretary, 11 Drumsheugh Gardens, Edinburgh EH3 7QQ not later than April 5, 1979.

143(A)

LECTURER IN PHARMACEUTICAL CHEMISTRY

Applications are invited for the post of Lecturer in Pharmaceutical Chemistry in the School of Pharmacy, Trinity College, Dublin.

Salary Scale: £4317-£8487. Appointment is likely to be made in the range £4317-£4774. There is a non-contributory pension scheme.

Interested persons should, in the first instance, telephone the Staff Office, Trinity College, on Dublin 772941 Ext. 1678/1775.

The closing date for receipt of applications will be 7th May 1979.

W7(A)

UNIVERSITY OF STRATHCLYDE DEPARTMENT OF MINING ENGINEERING PROFESSORSHIP AND HEAD OF THE DEPARTMENT OF MINING ENGINEERING

Applications are invited from appropriately qualified and experienced candidates for appointment to the Professorship and Head of the Department of Mining Engineering in succession to the late Professor J. Dewi Jenkins.

The post will be remunerated within the Professorial range for universities with U.S.S. benefits.

Application forms and further particulars (quoting 14/79) may be obtained from the Registrar, University of Strathclyde, Royal College Building, 204 George Street, Glasgow G1 1XW, with whom applications must be lodged by April 27, 1979.

170(A)

INSTITUTE OF TERRESTRIAL ECOLOGY HIGHER SCIENTIFIC OFFICER/ SENIOR SCIENTIFIC OFFICER

A vertebrate ecologist at Higher Scientific Officer/Senior Scientific Officer level is required to join a group studying the role of pollutants in the population dynamics of predatory birds, the work will involve research on sparrowhawks and kestrels.

The successful candidate will be based initially at the Institute in Edinburgh with the possibility of a move to ITE's Monks Wood Experimental Station near Huntingdon at a later date.

Qualifications

Candidates should have a good honours degree in zoology, biology or an allied subject and at least two years relevant post-graduate experience preferably in bird ecology. Applicants should be physically fit as duties include strenuous field work including tree climbing.

Salary and conditions of service

The salary will be within the following scales:-

HSO £4,101 to £5,448 per annum
SSO £5,154 to £6,898 per annum
with 22 days paid annual leave plus 10½ days public and privilege holidays. Starting pay according to age, qualifications and experience.

There is a non-contributory superannuation scheme.

The Natural Environment Research Council is not a Government Department but conditions of service are similar to those of the Civil Service. Application form and further details are available from:

Establishments Section
Institute of Terrestrial Ecology
68 Hills Road
Cambridge

CB2 1LA Telephone (0223) 69745

Please quote reference: 29.

Closing date for completed applications is: April 6, 1979. 164(A)

THE UNIVERSITY OF WESTERN ONTARIO LONDON—CANADA

Applications are invited for a one year limited term position from July 1, 1979 to June 30, 1980 at the rank of Assistant Professor to work with algae. Candidates will be expected to contribute to teaching in introductory biology in addition to teaching algology. Candidates will also be encouraged to pursue research in an area of algology of their choice. Post-doctoral experience would be an advantage. The salary will be not less than \$17,000 per annum, subject to the availability of funds. Please submit a curriculum vitae and the names of three referees to:

The Chairman
Department of Plant
Sciences
Biological and Geological
Building
University of Western
Ontario
London, Ontario
N6A 5B7. W10(A)

SALOP AREA HEALTH AUTHORITY ROBERT JONES AND AGNES HUNT ORTHOPAEDIC HOSPITAL Oswestry, Salop CHARLES SALT RESEARCH CENTRE BIOCHEMIST

Graduate Research Assistant required to take part in immunochemical investigations on human intervertebral discs in relation to Low Back Pain.

Salary scale (Basic Grade Biochemist with 1st or 2nd Class Honours Degree) £3,486 rising to £4,275 per annum.

Applications with names of two referees should be addressed to Mr N. W. Nisbet F.R.C.S., Director of Research, Charles Salt Research Centre, at the above hospital. 145(A)

UNIVERSITY OF DUNDEE

DEPARTMENT OF BIOLOGICAL SCIENCES

Applications are invited for two
LECTURESIPS

in Microbiology in the above Department. No field of interest is excluded but it is hoped that one post will be filled by someone with an interest in microbial/molecular genetics.

The posts are permanent and superannuable under U.S.S. Salary scale (under review) £3,883 to £7,754 with entry at points appropriate to the ages, qualifications and experience of the successful candidates.

Applications (six copies, overseas applicants one copy) quoting Reference EST/32/79X and naming three referees should be lodged as soon as possible with The Secretary, The University, Dundee DD1 4HN, from whom further particulars are available. 103(A)

LUDWIG INSTITUTE FOR CANCER RESEARCH (London Branch)

(in association with the Royal Marsden Hospital and the Institute of Cancer Research, Sutton, Surrey)

UNIT OF MOLECULAR BIOLOGY (Technical staff appointments)

A new cell and molecular biology unit is to be established shortly. Its interests will centre around experimental models of breast cancer.

CHIEF TECHNICIAN

is required: a wide experience of methods of tissue culture and light microscopy is essential and some knowledge of immunological techniques is desirable. While the duties of the post are largely practical, the successful candidate will also be expected to teach and train junior staff. Starting salary will be in the range £5,472 to £6,192, plus London Weighting, according to age and experience. Duties for this post will commence in the early summer.

RESEARCH OFFICERS/ TECHNICIANS

are also required with some previous experience of techniques of tissue culture and of molecular biology or protein biochemistry. Starting salary, probably within current range of £3,582 to £4,902 plus London Weighting (Research Officer), or £3,261 to £4,680 plus London Weighting (Technician). Duties for these posts will commence in the summer and the precise grading will depend on age, experience and qualifications.

Apply with full particulars and giving the names of two referees to The Secretary, Ludwig Institute for Cancer Research (London Branch), The Haddow Laboratories, Clifton Avenue, Sutton, Surrey SM2 5PX, before April 20, 1979. 167(A)

KING'S HEALTH DISTRICT (TEACHING) DENTAL SCHOOL SCIENCE GRADUATE OR BIOCHEMIST

Required for research project to study the cellular reactions to metallic alloys. This project should be suitable for a Ph.D. thesis. Experience in macrophage tissue culture and atomic absorption analysis methods desirable.

This post is tenable for one year in the first instance (to March 31, 1980), and is subject to annual renewal.

For an informal discussion about the post contact Mr B. Eley on 01-274 6222, extension 2834 or bleep. For job description and application form please contact the District Personnel Department, King's College Hospital, Denmark Hill, London SE5 9RS. Tel: 01-274 6222, extension 2254.

Closing date: April 6, 1979. 109(A)

THE OPEN
UNIVERSITY
FACULTY OF
SCIENCE

RESEARCH
TECHNICIAN

BIOPHYSICS RESEARCH GROUP,
OXFORD RESEARCH UNIT

Applications are invited for the post of Research Technician to assist in the study of the structure and transparency of the corneal stroma by a variety of biochemical and biophysical methods, working under the supervision of Professor G. F. Elliott at the Biophysics Research Group, Oxford Research Unit. Techniques used in the laboratory include X-ray diffraction, microelectrode measurements and gel electrophoresis. Computer experience might also be useful. The successful candidate will probably have a minimum of four years experience in a biochemical/biophysical laboratory.

The post is available for three years from 1st April 1979. Salary within the Technician Grade 5 scale £3,186-£3,720 p.a. (under review) according to experience.

Application forms and further particulars are available from The Recruitment Office (JD3812/1), The Open University, P.O. Box 75, Walton Hall, Milton Keynes, MK7 6AL or telephone Milton Keynes 63404: there is a 24 hour answering service on 63868. Closing date for applications: 5th April.

101(A)

LUDWIG INSTITUTE FOR
CANCER RESEARCH
(London Branch)

(in association with the Royal Marsden Hospital and the Institute of Cancer Research, Sutton, Surrey)

UNIT OF MOLECULAR BIOLOGY
Applications are invited from suitably qualified and experienced

BIOCHEMISTS

to fill one or other of two appointments in the new Unit which will be established shortly under Dr P. S. Rudland. The principal focus of research will be on experimental aspects of mammary cancer.

For post (a), previous experience of protein and nucleic acid biochemistry is essential.

For post (b), previous experience of protein purification techniques and cell biology is essential.

Further particulars may be obtained from the address given below. Candidates for these appointments, which will commence in or before September 1979, should have gained appropriate postdoctoral experience which will be reflected by the salaries likely to be offered £5,129 to £6,080, plus London Weighting (equivalent to M.R.C. non-clinical Scientific Grade II). The appointments will be for an initial period of three years. University Superannuation Scheme available.

Apply with curriculum vitae and names of two referees to The Secretary, Ludwig Institute for Cancer Research (London Branch), The Hadow Laboratories, Royal Marsden Hospital, Belmont, Surrey SM2 5PX, before April 27, 1979. 166(A)

POSTDOCTORAL RESEARCH

Applications from Ph.D. graduates in Immunology or related area interested in studying regulatory mechanisms of the immune system and tumour immunity.

Salary is \$13,000 for the first year and \$13,800 for the second.

Send curriculum vitae and references to: Dr I. A. Ramshaw, Department of Microbiology, University of Saskatchewan, Saskatoon, Saskatchewan, Canada S7N 0W0. W16(A)

CSIRO

AUSTRALIA

Postdoctoral Research Fellows

Fuel Geoscience Unit North Ryde, NSW

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

General: The Fuel Geoscience Unit conducts research relevant to exploration for the fossil fuels—coal, petroleum, natural gas and oil shale—and to their assessment and extraction.

Field: Coal Mine Geology—Ref. No. 602/063

Duties: To initiate and conduct research aimed at generating information relevant to coal mining prior to the construction of mine openings. The appointee will be, or should become, familiar with geological factors of importance in underground coal mining and will be required to apply some of the techniques of sedimentary (including coal) petrology and engineering geology to studies of drill core and other samples.

Qualifications: A Ph.D. or equivalent qualifications in a relevant area of geology. Experience appropriate to duties above, especially concerning the significance of the physical properties of rocks to mining practice would be an advantage.

Field: Gas in Coal Seams—Reference No. 602/060

Duties: To initiate and conduct research, within a team, into the nature and cause of gaseous outbursts in coal mines. The appointee will be required to investigate the physical and chemical constitution of coal and coal measure rocks as these relate to the occurrence and severity of outbursts and their prediction and possible prevention.

Qualifications: A Ph.D. or equivalent qualifications in a relevant field such as Geochemistry or Physical Chemistry. Familiarity with mining or geology of coal would be an advantage.

Field: Coal Utilization—Ref. No. 602/066

Duties: To initiate and conduct, within a team, research directed towards making the most

effective use of Australian coal resources, with special emphasis on conversion of coals to liquid fuels. The appointee will be required to use petrological techniques to study the properties of coals and of products obtained from coals after treatment.

Qualifications: A Ph.D. or equivalent qualifications together with interest and experience in the fields of coal petrology and coal chemistry.

Field: Coal Science—Ref. No. 602/067

Duties: The successful applicant will be required to initiate and conduct research into the physical and chemical character of coals and coal derivatives as part of a project on the fundamentals of obtaining liquid fuels from Australian coals. It is expected that this research will make considerable use of NMR studies. A Bruker CXP 100 NMR spectrometer, suitable for both high power and high resolution techniques is available for this work. A high temperature specimen probe is on order.

Qualifications: A Ph.D. degree or equivalent qualifications in physics or chemistry, with considerable experience in relevant fields of nuclear magnetic resonance spectroscopy. Experience with coal or related materials would be an advantage.

Salary: Research Scientist/Senior Research Scientist: \$A15,422—\$A22,405 p.a.

Tenure: Appointment to these positions will initially be for a period of twelve months with the possibility of extension.

Applications in duplicate, stating full personal and professional details, the names and addresses of at least two professional referees, and quoting the appropriate reference number(s) should reach: The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maltravers Street, LONDON WC2R 3EH by 21st April, 1979.

Applications in U.S.A. and Canada should be sent to: The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue N.W., WASHINGTON D.C. 20036. 158(A)

THE
QUEEN'S UNIVERSITY
OF BELFAST
CHAIR OF ZOOLOGY

Applications are invited for the Chair of Zoology which will become vacant on October 1, 1979 on the appointment of Professor G. Owen as Principal of University College of Wales, Aberystwyth. The salary of the Chair is £10,575 per annum (under review) with contributory pension rights under F.S.S.U. or U.S.S.

Further particulars may be obtained from the Personnel Officer, The Queen's University of Belfast, BT7 1NN, Northern Ireland. Closing date: April 27, 1979. (Please quote Ref. 79/N.) 104(A)

UNIVERSITY OF
BIRMINGHAM
DEPARTMENT OF
CANCER STUDIES
POSTDOCTORAL
RESEARCH FELLOW

is required to join a team of scientists studying the proteins of normal and transformed cells. The project will be of three years' duration and the successful candidate will be expected to have a good biochemistry background and a working knowledge of protein separation techniques. Salary will be in the range £3,883 to £6,555. Applications, giving a full curriculum vitae, a copy of the synopsis of their Ph.D. thesis and the names of two academic referees, should be sent to Professor D. G. Harnden, Department of Cancer Studies, Medical School, University of Birmingham B15 2TJ. 119(A)

UNIVERSITY OF
EDINBURGH
POSTGRADUATE
STUDENT

A vacancy will arise in October 1979 for a postgraduate interested in working in the field of mode of action of drugs and investigating the possibility of separating the contributions of efficacy and affinity to the action of drugs at H₁ and H₂ receptors.

Please send applications giving full curriculum vitae and names of referees to:

Professor E. W. Horton,
Department of Pharmacology,
1 George Square,
Edinburgh EH8 9JZ. 116(A)

**Forestry Commission, Northern
Research Station, Roslin,
Edinburgh**

Entomologist

... to join a small team conducting research into the relationship between the pine beauty moth *Panolis flammea* and its host lodgepole pine and the forest environment. The work will involve making a detailed study of the life cycle of the insect and its natural enemies, investigating the influence of lodgepole pine phenology and climatic variables in the development of populations, and examining the biological importance of host nutritional factors affecting the insect. In addition, the entomologist will study the results of these experiments to assess the factors responsible for population changes.

Candidates, normally aged under 32, should have a good honours degree or equivalent in Zoology or Forestry and at least 2 years' postgraduate experience in entomology.

Appointment as Senior Scientific Officer (£5150-£6900) or Higher Scientific Officer (£4100-£5450) according to qualifications and experience. Salaries under review. Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by 12 April 1979) write to Personnel Branch, Forestry Commission, 231 Corstorphine Road, Edinburgh, EH12 7AT. Please quote ref: SA/9/DM.

Plant Pathology Laboratory

Entomologist

The Laboratory, at Harpenden, provides the scientific basis for the introduction and administration of legislation intended to prevent the start or further spread of dangerous plant diseases and pests.

This post is in the Entomology Department where the successful candidate will join a team working on the elimination of pests from imported herbaceous planting material and woody plants. This work will involve developing chemical and physical methods of treatment and liaison with importing firms.

Candidates, normally aged under 27, should have a good honours degree or equivalent in Biology, preferably including specialised studies of entomology or pest control.

Appointment as Scientific Officer (£2840-£4410; under review) with starting salary according to qualifications and experience. Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by 17 April 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). Please quote ref: SB/23/AG.

**Ministry of Agriculture,
Fisheries and Food**

ALL THESE POSTS ARE OPEN TO MEN AND WOMEN.

**Ministry of Agriculture,
Fisheries and Food,
Food Science Division, London**

Food Scientists and Nutritionists

These posts are in the Nutrition Section which assists the Division in providing an advisory service on all aspects of food science, food technology and human nutrition, both at home and abroad.

Nutrition and Food Composition Studies

The scientist appointed will supervise the collection and interpretation of information on the nutrient content of food. This work will involve close liaison with statisticians, food manufacturers, caterers and dieticians to determine needs and priorities and the commissioning of analytical work on foods. In addition, the successful candidate will act as secretary to a committee on the composition of food and food products.

Candidates, normally aged under 32, should have a good honours degree or equivalent in an appropriate discipline, coupled with at least 4 years' relevant experience. The ability to evaluate information on nutrition and food composition and a familiarity with data processing is highly desirable.

Appointment as Senior Scientific Officer (£5675-£7420; under review) with starting salary according to qualifications and experience. Promotion prospects. Non-contributory pension scheme. Ref: SB/37/AE.

Analysis of Material for the National Food Survey

The successful candidate will join a team involved in analysing trends in food consumption and processing methods and assessing the effects on nutrient intake. In addition, the scientist will liaise with Government Departments, Research Councils and Industry to provide information for Ministerial briefs and the general public.

Candidates, normally aged under 27, should have a good honours degree or equivalent in human nutrition or related discipline. Experience of data processing is highly desirable. *Final year students may apply.*

Appointment as Scientific Officer (£3360-£4940; under review) with starting salary according to qualifications and experience. Promotion prospects. Non-contributory pension scheme.

Ref: SB/38/AE.

For further details and an application form (to be returned by 18 April 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). Please quote appropriate reference.

UNIVERSITY OF OXFORD

DEPARTMENT OF ZOOLOGY

EDWARD GREY INSTITUTE OF FIELD ORNITHOLOGY

Applications are invited for the post of Departmental Demonstrator in the above Institute from September 1, 1979. The successful candidate, who should recently have received a Ph.D. or be in his final year before submission, will be required to take part in departmental teaching and to undertake research in field ornithology. The salary will be within the University scale—£3,384 to £4,466 p.a. with membership of U.S.S.

Applications, including the names of two referees, should be submitted to the Director, Edward Grey Institute of Field Ornithology, Department of Zoology, South Parks Road, Oxford OX1 3PS by April 30, 1979. 152(A)

**UNIVERSITY OF READING
PROFESSORSHIP OF
SOIL SCIENCE**

Applications are invited for the Professorship of Soil Science, which is vacant as a result of the resignation of Professor D. J. Greenland.

Candidates should be sympathetic to the dual nature of the Department of Soil Science (which is concerned both with the fundamental aspects of Soil Science and with its relationship with agricultural, biological and other sciences) and be capable of maintaining and developing its work along these lines.

The appointment will be made from a date to be arranged with the successful candidate.

Further information may be obtained from the Registrar (Room 214, Whiteknights House), The University, Whiteknights, Reading RG6 2AH, by whom applications should be received not later than April 21, 1979. 113(A)

**UNIVERSITY OF LIVERPOOL
DEPARTMENT OF BIOCHEMISTRY**

Applications are invited for the

POSTDOCTORAL

SENIOR

RESEARCH ASSISTANT

in the Department of Biochemistry. The post is funded by a grant from the North West Cancer Research Fund to study the hormone responsiveness of a line of human breast cancer cells. Experience of tissue culture would be an advantage.

The initial salary will be within the range £3,883 to £4,882 per annum (Senior Research Assistant Ia). The appointment will be for one year in the first instance.

Applications, together with the names of two referees, should be received not later than April 13, 1979, by The Registrar, The University, Liverpool L69 3BX. Quote Reference RV/525/N. 110(A)

**UNIVERSITY OF
ASTON IN BIRMINGHAM
DEPARTMENT OF METALLURGY
AND MATERIALS**

ARCHAEO-METALLURGIST

Applications are invited for a Research post in archaeometallurgy from candidates with at minimum a good first degree in an applied physical science, together with some knowledge of microstructural methods of analysis and of archaeology. The appointment is supported by the Department of the Environment through its Ancient Monuments Laboratory and will involve:

- the investigation of archaeological finds of metallurgical significance;
- the development of suitable techniques for such investigation;
- research in the areas of provenance and technology in relation to early metallurgical operations.

Commencing salary will be within the range £3,883 to £4,631 per annum.

Application forms and further details may be obtained from the Staff Officer (quoting Ref. No. 346/N), University of Aston in Birmingham, Gosta Green, Birmingham B4 7ET (Tel. 021 359 3611, Ext. 201) and applications should be returned not later than Friday, April 13, 1979. 111(A)

**CITY OF LONDON
POLYTECHNIC
DEPARTMENT OF BIOLOGICAL
SCIENCES
ELECTRONICS TECHNICIAN
GRADE 5**

The City of London Polytechnic require, as soon as possible, an Electronics Technician for the design and construction of electronic physiological and neurophysiological apparatus for teaching and research, together with day-to-day servicing of neurophysiological teaching laboratory, and supervision of the electronics workshop. Candidates should possess an H.N.C. in an appropriate field.

The vacancy exists in our Biological Sciences Department which is located at Calcutta House, Old Castle Street close to Aldgate and Aldgate East Underground stations.

Starting salary, which will depend on qualifications and experience, will be within the scale of £3,675 to £4,212 inclusive (under review).

Further details and an application form can be obtained from the Staff Records Officer, City of London Polytechnic, 117/119 Houndsditch, London EC3A 7BU. Please quote reference number 79/18. 148(A)

**UNIVERSITY OF BRISTOL
Long Ashton Research Station
ENVIRONMENTAL
PHYSIOLOGIST**

Required in the Microclimatology Section to study the effects of disease on the physiology of cereals in the laboratory and field. The post requires knowledge of whole-plant physiology (growth analysis, photosyntheses measurements etc.) and of micro-meteorology. Experience with instruments and a high degree of numeracy an advantage.

Appointment in the Scientific Officer grade (£2,893 to £4,415 per annum). Starting salary dependent on qualifications and experience. Non-contributory superannuation scheme.

Qualifications
Honours degree or equivalent in Botany, Applied Botany or Agricultural Botany, or an ordinary degree with relevant experience.

Applications
Written applications should be sent to the Secretary, Long Ashton Research Station, Long Ashton, Bristol BS18 9AF, by not later than April 12, 1979. 147(A)

**UNIVERSITY OF DUBLIN
Trinity College**

**Temporary Lecturer
in Physics**

Applications are invited for the above post for the academic year 1979/80.

Salary scale: £4,317 to £8,487. Appointment will be made within the range £4,317 to £4,774.

Interested persons should, in the first instance, telephone the Staff Office, Trinity College, on Dublin 772941 Ext. 1678/1775.

The closing date for receipt of applications will be April 16, 1979. W12(A)

**UNIVERSITY OF
NEWCASTLE UPON TYNE
BIOLOGICAL CONSERVATION
AND POLLUTION STUDIES**

Applications are invited for appointment to a newly established

LECTURESHIP

Applications are invited for a Science in the Faculty of Agriculture from well qualified persons with research experience in either biological conservation or pollution studies in the countryside. The main teaching duty will involve a contribution to courses in one of the above subjects: the interdepartmental Honorary Degree in Agricultural and Environmental Science.

Salary will be at an appropriate point on the Lecturers' scale: £3,883 to £7,754 per annum, according to age, qualifications and experience. Membership of the appropriate University superannuation scheme will be required.

Further particulars may be obtained from the Senior Assistant Registrar, The University, 6 Kensington Terrace, Newcastle upon Tyne, NE1 7RU, with whom applications (3 complete copies together with the names and addresses of 3 referees, should be lodged not later than May 1, 1979. Please quote reference N. 137(A)

**UNIVERSITY OF KENT
AT CANTERBURY
LECTURER AND
TUTORIAL FELLOW
IN BIOCHEMISTRY**

Applications are invited for appointment to a Lectureship and Tutorial Fellowship in Biochemistry, both of which become vacant on October 1, 1979, the former because of the appointment of the holder, Dr C. Pegg, to a Chair. Preference will be given to candidates whose research interests and experience are in mammalian biochemistry.

It is expected that the Lecturer will be appointed within the first six points of the scale £3,883 to £7,754 and the Tutorial Fellowship, which is for a fixed term of three years, will be filled within the first three points of the scale £3,883 to £6,555.

Application forms and particular may be obtained from the Senior Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT7 7NH, to whom completed application should be returned by April 13, 1979. Please quote ref. A21/79. 140(A)

TECHNISCHE HOGESCHOOL-DELFT

The Faculty of Chemistry and Chemical Engineering of the Delft University of Technology invites applications for the position of

FULL PROFESSOR OF MICROBIOLOGY

Microbiology, biology and technology are being integrated to establish a single group for biotechnology. The successful candidate will be expected to direct his/her teaching and research towards both applied and fundamental aspects of microbiology. Close cooperation with other colleagues concerned with biotechnology will be required.

Teaching: The professor will be responsible for lectures and courses in General Microbiology, Industrial Microbiology, Microbiology of Water and Wastewater, possibly Cell Biology and Microbial Genetics. The supervision of experimental work carried out by undergraduate and graduate students will also be involved.

Research: Experimental work will be concerned with microbiological systems related to industrial processes and environmental control. In addition the task includes the supervision of basis research by some staff members.

Administrative duties: The successful applicant will be expected to participate actively in the administrative tasks of the Microbiology Group and the Faculty. Additional information will gladly be supplied by the Chairman of the Appointing Committee.

Applications, including curriculum vitae, giving full details of qualifications, experience and names of at least two referees should be addressed to the Chairman of the Appointing Committee, Prof. N. W. F. Kossen, c/o Bureau van de Afdeling der Scheikundige Technologie, postbus 5045, 2600 GA Delft, The Netherlands.

W3(A)

THE QUEEN'S COLLEGE, GLASGOW SENIOR LECTURESHIP IN MICROBIOLOGY AND BIOCHEMISTRY

Salary Scale: £7,155 to £7,962 (Bar) to £9,042 per annum

Applications should have an Honours Degree in Microbiology, Biology or Chemistry, and a Higher Degree, preferably in Microbiology.

The successful candidate would be expected to play a major role in course development, research and administration within the Department of Science, as well as teaching on a wide range of courses.

Further details and application forms may be obtained from:

The Principal,
The Queen's College, Glasgow,
1 Park Drive,
Glasgow G3 6LP.

Closing date for applications: April 20, 1979.

118(A)

THE CITY UNIVERSITY DEPARTMENT OF CHEMISTRY Applications are invited for the newly established CHAIR OF INDUSTRIAL CHEMISTRY

The salary will be in the range for professorial appointments and there will be a London Allowance of £450 per annum. Superannuation will be in accordance with the provisions of U.S.S.

Further particulars may be obtained from the Academic Registrar, The City University, Northampton Square, London EC1V 0HB. The closing date for applications is May 3, 1979. Please quote ref. C/235/N. 106(A)

UNIVERSITY OF OXFORD M.R.C. UNIT FOR MOLECULAR HAEMATOLOGY. Research Assistant is required to join a newly formed M.R.C. Unit working on hereditary disorders of Human Haemoglobin Structure and Synthesis. The work involves isolation and assay of mRNA, and the characterisation of mutant globin genes by restriction endonuclease mapping and recombinant DNA techniques. Candidates should possess a degree in Biochemistry, Chemistry or a Related Scientific subject. Experience in nucleic acid research desirable but not essential. Salary on the Oxford University Research Staff Grade 1a (at present under review) £3,383 to £6,555 per annum depending upon age and experience. Application forms and further details may be obtained from: The Departmental Administrator, Nuffield Department of Clinical Medicine, Radcliffe Infirmary, Oxford. 181(A)

UNIVERSITY OF THE WITWATERSRAND, Johannesburg, South Africa DEPARTMENT OF BIOCHEMISTRY SENIOR LECTURER/ LECTURER

Applications are invited from suitably qualified persons for appointment to the above post. Applicants are expected to have a Ph.D. or equivalent and appreciable research experience.

The salary ranges are as follows:

Senior Lecturer:

R10,144 to R13,489 per annum

Lecturer:

R7,554 to R11,007 per annum

A salary review is expected in April, 1979.

The initial notch and level of appointment will be determined in accordance with the qualifications and experience of the successful applicant.

The University's policy is not to discriminate in the appointment of staff or the selection of students on the grounds of sex, race, religion or colour. Further particulars relating to this practice and the above post are included in an information sheet obtainable from the London Representative, University of the Witwatersrand, Chichester House, 278 High Holborn, London WC1V 7HE, or from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, 2001 South Africa, with whom applications should be lodged by April 12, 1979. 128(A)

MEDICAL RESEARCH COUNCIL NATIONAL INSTITUTE FOR MEDICAL RESEARCH DIVISION OF BIOCHEMISTRY A POSTDOCTORAL

position will be available in the autumn to work with Dr Ian Kerr on the control of macromolecular synthesis and cell growth with particular reference to the antiviral and antitumour effects of interferon. Current interests are centred on the role of protein kinases and the oligonucleotide effector pppA₅p₅A₂p₅A in interferon-treated cells and the possible wider significance of the latter in normal cell growth and development.

Applicants should have either a Ph.D. or complete the requirements for one in the near future.

The appointment will be for up to three years and will be in the salary range £4,408 to £6,080 per annum according to age and qualifications, plus £450 per annum London Allowance. Superannuation provision.

Applications, giving details of qualifications, experience and the names of two professional referees, should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA, before April 30, 1979, quoting reference B/1. 171(A)

UNIVERSITY OF DUBLIN
Trinity College

LECTURER IN PHARMACEUTICS

Applications are invited for the above post in the Department of Pharmaceutics, School of Pharmacy, Trinity College, Dublin.

Salary Scale: £4317-£8487. Appointment is likely to be made in the range £4317-£4774. There is a non-contributory pension scheme.

Interested persons should, in the first instance, telephone the Staff Office, Trinity College, on Dublin 772941 Ext. 1678/1775.

The closing date for receipt of applications will be 7th May 1979.

W8(A)

THE UNIVERSITY OF LEEDS DEPARTMENT OF ORGANIC CHEMISTRY

Applications are invited from suitably qualified candidates for the post of LECTURER in the above department, available from April 1, 1979. Candidates should have special research interests in the chemistry of natural products, particularly in bioactive molecules.

Salary on the scale for lecturers: £3,883 to £7,754 (under review), according to age, qualifications and experience.

Applications (quoting reference number 45/8/D), giving details of research interests and an account of the chemistry that the candidate would like to pursue, with a curriculum vitae and the names and addresses of three referees, should be made no later than April 30, 1979 to the Registrar, The University, Leeds LS2 9JT (from whom further particulars may be obtained). 144(A)

UNIVERSITY OF NATAL DEPARTMENT OF BIOLOGICAL SCIENCES DURBAN

Applications are invited from suitably qualified persons regardless of sex, religion, race, colour or national origin for appointment to the post of

LECTURER

in the Department of Biological Sciences.

The present salary scale attached to the post is: R6,300 by R30 to R9,180, plus a pensionable allowance of 19.9% of basic salary and it is expected that salaries will be increased from April 1, 1979.

Preference will be given to candidates with research and teaching experience in the field of quantitative plant ecology, with emphasis on plant/herbivore interactions and the assessment of habitat condition and trend. As well as participating in the normal teaching programme, the incumbent of the post will be expected to engage and supervise research in one of the above fields.

The commencing salary notch will be dependent on the qualifications and/or experience of the successful applicant. In addition, an annual vacation savings bonus is payable, subject to Treasury regulations.

Application forms, further particulars of the post and information on pension, medical aid, group insurance, staff bursary, housing loan and subsidy schemes, long leave conditions and travelling expenses on first appointment are obtainable from the Registrar, University of Natal, King George V Avenue, Durban, 4001, with whom applications, on the prescribed form, must be lodged not later than April 30, 1979, quoting the reference Adv. D13/79. W4(A)

UNIVERSITY OF GLASGOW RESEARCH ASSISTANT

Applications are invited for the post of research assistant in the Department of Veterinary Pathology, University of Glasgow Veterinary School, Bearsden Road, Glasgow G61 1QH, to undertake studies on immunity in the respiratory tract of the dog with special reference to the prophylaxis of canine respiratory disease. Applicants should have, or expect to gain, a good honours degree in immunology or another relevant biological science. The successful applicant may apply to study for a postgraduate degree.

The appointment, which is funded by the Wellcome Trust, will be for three years and will be superannuated. Salary will be within the range £3,883 to £4,382 of the scales for Research and Analogous Staff.

Applications with the names of two referees should be submitted to Dr I. A. P. McCandlish at the above address, from whom further particulars can be obtained. Closing date for applications: March 30, 1979.

In reply please quote Ref. No 4405M. 175(A)

GEOSCIENTIST

The Whiteshell Nuclear Research Establishment, Pinawa, Manitoba has a vacancy for a Geoscientist to join a multi-disciplinary group verifying the concept of deep underground disposal of nuclear wastes. The job will involve specifically ensuring that backfilling, chemical buffering and sealing of a vault in hard rock are given appropriate attention within an overall research and development programme. This will include (1) supervising contracts with outside organizations such as government agencies and departments, consultants and universities; (2) setting up an experimental programme within AECL; (3) providing the necessary geotechnical expertise to ensure that all laboratory scale tests and experiments are representative of the geologic reality; (4) help to design tests of a scale appropriate for the demonstration of safe disposal of nuclear wastes in appropriate geologic formations.

The successful candidate should have a PhD or MSc degree in one of the Geosciences and a good background in Chemistry. Experience with clay minerals, radioactive tracers, computer modelling techniques, mining engineering, backfilling or sealing of mines or boreholes are all desirable but not necessarily essential. Preference will be given to candidates with the personal qualities and experience necessary to both supervise contracts and work in a team or group situation.

Starting salaries will be commensurate with qualifications and experience. AECL has a comprehensive benefits package and relocation assistance is provided.

The Whiteshell Nuclear Research Establishment employs approximately 800 people and is located about 105 km northeast of Winnipeg near the Whiteshell resort area. Pinawa is a modern townsite about 15 km from WNRE.

Men and women who may be interested in this position and possess the necessary qualifications should apply in writing giving full particulars to Personnel Supervisor, Atomic Energy of Canada Research Company,

WHITESHELL NUCLEAR RESEARCH ESTABLISHMENT PINAWA, Manitoba, ROE 1LO.

L'Énergie Atomique
du Canada, Limitée

Atomic Energy
of Canada Limited

W15(A)

UNIVERSITY OF EDINBURGH DEPARTMENT OF BOTANY Applications are invited for a POSTDOCTORAL RESEARCH FELLOW

to work with Dr. A. Trewavas on a three-year project supported by the A.R.C. The work will involve preparation of cDNA to cellulase mRNA to investigate the mechanisms of transcriptional control induced by auxin. Experience of techniques in this area of work would be an advantage but is not essential.

Salary is on the scale £3,883 to £6,555 per annum.

Applications (C.V. and two referees) may be made to Dr A. Trewavas, Department of Botany, The King's Buildings, Edinburgh, EH9 3JH, from whom further details may be obtained. Please quote Reference 5011. 115(A)

UNIVERSITY OF LONDON GOLDSMITHS' COLLEGE New Cross, London, SE14 6NW SCHOOL OF SCIENCE AND MATHEMATICS DEPARTMENT OF GEOLOGY Applications are invited for a LECTURERSHIP IN GEOLOGY

which is available from September 1, 1979. Applicants should be currently carrying out research work in one or other of the following fields: geochemistry/economic geology or economic stratigraphy.

Salary on scale £4,575 by 12 increments to £7,539 per annum inclusive of London Allowance.

Write for further details, to the Personnel Officer, to whom applications should be sent by April 12, 1979. 176(A)

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF GENETICS
Applications are invited for the post of Grade 2B Laboratory Technician in the Department of Genetics to help with laboratory classes and assist generally as required. Applicants should possess ONC/OND qualifications or 2 'A' levels in appropriate science subjects or Part I City & Guilds Science Laboratory Technician Certificate. Experience of working in either school or University laboratories would be an advantage. Preference given to candidates experienced in Microbial techniques.

Salary in the range of £2,529 to £2,880 per annum (under review).

Application forms can be obtained from the Establishment Officer, University of Nottingham, University Park, Nottingham NG7 2RD. Telephone Nottingham 56101 extension 3397. Please quote reference No. GN. 3/79. 161(A)

UNIVERSITY OF EDINBURGH RESEARCH ASSOCIATE

Applications are invited from Honours graduates in Botany or Microbiology to work on a project investigating the efficiency of nitrogen fixation in legume root nodules. The project is funded by the A.R.C. and is under the supervision of Dr R. O. D. Dixon. The post will be tenable for three years from May 1, 1979. The salary is in the range £3,384 to £4,133 per annum.

Applications should be submitted by April 10, 1979 to Dr R. O. D. Dixon, Botany Department, The King's Buildings, Mayfield Road, Edinburgh EH9 3JH. Please quote Reference 5012. 114(A)

Recombinant DNA Research

Genentech, the leading company in the application of recombinant DNA techniques to problems in human health care, is expanding its research program and has opportunities for outstanding scientists.

Qualified individuals will be joining an innovative research team working in a unique scientific environment. Genentech offers the scientific freedom to develop and direct your own independent research program and the intellectual stimulation of interacting with quality associates while contributing to the understanding and expansion of this new technology.

Senior Protein Recovery Scientist/Bioengineers. Opportunities exist to participate in the development of new procedures for the recovery and purification of polypeptides from microorganisms. A Ph.D. or equivalent in biochemistry or bioengineering plus at least three years relevant post-doctoral or industrial experience is required.

Senior Level Positions. Openings are available for biochemists, microbiologists, molecular biologists, molecular immunologists, and protein chemists. Applicants should have a Ph.D., postdoctoral research experience, and an outstanding research record.

Postdoctoral Position. Genentech has a postdoctoral research program. Opportunities exist for participation in ongoing projects or for initiation of new basic research projects. The two year appointments carry a first year salary of \$15,000.

Support Positions. B.S. or M.S. level biochemists with expertise in nucleic acids or protein chemistry are invited to apply.

Genentech offers an exceptional working environment and an outstanding compensation and benefits package. Please send curriculum vitae, reprints of pertinent publications, and a list of three references to Personnel Department, Genentech, Inc., 460 Point San Bruno Boulevard, South San Francisco, California 94080.

We are an equal opportunity employer.

W11(A)

CSIRO AUSTRALIA

Postdoctoral Research Fellow

Division of Food Research North Ryde NSW

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field: Plant Physiology

General: The research programmes of the Division include many aspects of the physical and biological sciences related to the handling, processing and storage of foods and to the needs of the food industry and the consumer. The Plant Physiology Group within the Food Research Laboratory at North Ryde, NSW, is conducting major investigations into the pre- and post-harvest physiology and biochemistry of plants and their fruits.

Duties: The appointee will join a group of plant biochemists and physiologists who are studying the effects of temperature, particularly in the chilling range, on plants and their fruits. The appointee will develop methods of determining chilling injury in plants suitable for application in plant breeding programmes to increase chilling resistance.

Qualifications: A PhD or equivalent in an appropriate field and proven research ability. It is expected that the appointee will be a plant physiologist/biochemist with a demonstrated interest in genetics or plant breeding, or a geneticist/plant breeder with a strong background in plant physiology or biochemistry.

Salary: Research Scientist: \$A15,422—\$A18,904 p.a.

Tenure: This position is available for a period of one year with the possibility of an extension to two years.

Applications in duplicate, stating full personal and professional details, the names and addresses of at least two professional referees, and quoting reference number 300/716 should reach: The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by April 21, 1979. Applications in U.S.A. and Canada should be sent to:—The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A. 160(A)

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

(UNIVERSITY OF LONDON)

Keppel Street, WC1E 7HT

Lecturer/Senior Lecturer in Virology

Applications are invited for the above post in the Arbovirus unit of the Departments of Entomology and Medical Microbiology. Candidates should have gained a Ph.D. in Virology or a related discipline, or a medical degree, and should have at least 5 years' experience in different aspects of virus research such as tissue culture, serology and animal models. Field experience, although not essential, is desirable, and the successful candidate will be expected to undertake visits abroad at short notice if necessary.

The appointment will be made within the salary scales for university Lecturers (£3,883 to £7,754) or Senior Lecturers (£7,506 to £9,263) or the appropriate scale for clinically qualified staff. The post will be tenable at the Field Station at St Albans. Application forms, which should be returned by May 17, and further information can be obtained from F. C. Ball, Assistant Secretary at the School. 146(A)

UNIVERSITY OF DUBLIN
Trinity College

Environmental Sciences Unit

LECTURESHIPS

The Environmental Sciences unit has the function of encouraging interdisciplinary research and postgraduate teaching especially between the Departments of Botany, Geography, Geology, Microbiology and Zoology.

Applications are invited for two Lectureships in Environmental Sciences. Ideally, candidates should have research or applied experience in one of the following areas:

Whole Ecosystem field studies: Microbial aspects of Ecology:

Applied Pollution Ecology: Ecological Systems Analysis:

Geochemistry of Contemporary Sediments.

Salary Scale: £4,317 to £8,487 p.a. Appointment, in the case of each lectureship, is likely to be made within the range £4,317 to £4,774 p.a. There is, in addition, a non-contributory pension scheme.

Persons interested in making application for these posts should, in the first instance, Telephone the Staff Office, Trinity College, on Dublin 772941 ext. 1678/1775.

The closing date for receipt of completed applications will be April 16, 1979. W14(A)

UNIVERSITY OF BRISTOL

Applications are invited for the post of **LECTURER IN ANATOMY**

A vacancy exists for a lecturer with a primary responsibility to the teaching of medical students. As well as being responsible for the teaching of gross anatomy to medical, dental, veterinary and science students, the Department offers courses in neuro-anatomy, endocrinology, reproduction, embryology, dental anatomy and physical anthropology, with specialised teaching in each of these topics to an honours degree level.

The Department has excellent facilities for research and is presently organised into a number of research groups working in the following areas: biochemistry and physiology of peptide-secreting neurones, neuroanatomy of dopamine pathways, electrophysiology of the C.N.S., control of parturition, bone mechanics, tooth eruption and physical anthropology.

Salary will be on the scale £3,883 to £7,754 (under review) and letters of application including the names and addresses of three referees should be sent to the Registrar and Secretary, University of Bristol, Senate House, Bristol BS8 1TD, before May 18, 1979 (quoting ref. TLJ). Interested persons are welcome to visit the department by arrangement with the Head of Department's secretary (Tel: 0272-24161, Extension 367). 141(A)

UNIVERSITY OF BRISTOL RESEARCH ASSISTANT

Applications are invited from graduates or students about to graduate in Physiology, Zoology or a related science who would like to join an active research group using electrophysiological methods to investigate the role of the nervous system in labour, lactation and other aspects of mammalian reproduction. A detailed knowledge of electrophysiological recording methods is not essential.

The appointment is funded by the Medical Research Council for three years at a commencing salary of £3,384 (Range 1B) (scale under review).

Applications giving details of age, qualifications and the names of two referees should be sent by April 20, to Dr D. W. Lincoln, The Medical School, University Walk, Bristol BS8 1TD, from whom further particulars are available (Tel: Bristol 24161, ext. 557). 154(A)

UNIVERSITY OF CAMBRIDGE/ ROYAL BOTANIC GARDEN EDINBURGH RESEARCH ASSOCIATE IN PLANT TAXONOMY

Applications are invited for a Research Associate to help in the preparation of a new Flora of Cultivated Plants. This post is funded by a grant from the Stanley Smith Horticultural Trust and will be for two years with a possible extension for a third year. Applicants should have a Ph.D. in higher plant taxonomy or equivalent experience. Salary, based on the S.R.C. 1A scale, ranging from £3,883 to £4,882 per annum. The successful candidate will work for the most part at the Royal Botanic Garden Edinburgh.

Send curriculum vitae (three copies) and names of two referees to: Dr S. Walters, University Botanic Garden, Cambridge CB2 1JF. Closing date: April 16, 1979 132(A)

UNIVERSITY OF SURREY DEPARTMENT OF METALLURGY AND MATERIALS TECHNOLOGY CHEMIST or PHYSICIST

A vacancy has arisen in the Department of Metallurgy and Materials Technology for a chemist or physicist to work on the surface chemistry of carbon fibres with Dr W. Watt, F.R.S.

The work will involve the desorption of surface species with increasing temperature, their identification and quantification with mass spectrometry and interpretation of results. High vacuum, mass spectrometry and surface chemistry techniques are involved. The work should be of interest to a graduate or post doctorate wishing to gain experience in these important fields and their application to the surface chemistry of high strength high modulus carbon fibres.

The apparatus is fully functional. Many results have already been obtained and the work has reached a very interesting stage. Liaison will be maintained with Materials Department, Royal Aircraft Establishment.

The appointment will be for one year with starting date as soon as possible.

Salary will be in the range £3,384 to £4,133 for graduate or £4,382 to £5,122 for postdoctorate, with starting point dependant on qualifications.

Applications, with full curriculum vitae, to:

Professor J. E. Bailey,
Department of Metallurgy
and Materials Technology,
University of Surrey,
Guildford, Surrey GU2 5XH.

126(A)

THE UNIVERSITY OF MANCHESTER EXPERIMENTAL OFFICER DEPARTMENT OF PHARMACY

The person appointed will be responsible for the development and co-ordination of analytical techniques in research dealing with pharmacokinetics, drug metabolism and toxicology. The techniques primarily involve the use of chromatography, spectroscopy and radioactivity. The successful candidate will also help plan and run kinetic experiments in animals and man, and help in processing the data using computational techniques.

Applicants must be graduates in either chemistry, biochemistry, or a related science, with a minimum of two years' relevant experience post degree.

Initial salary in the range per annum £3,384 to £5,604, superannuation under U.S.S.

Particulars and application form (returnable by April 20) from the Registrar, The University, Manchester M13 9PL. Quote reference: 38/79/N 177(A)

**QUEEN ELIZABETH
COLLEGE**
Kensington
(University of London)
DEPARTMENT OF
MATHEMATICS
Part-time
LECTURERS

required, in session 1979-80 only, to teach two courses to first year students. One course is **CALCULUS AND ALGEBRA** and the other is **MECHANICS**. Each involves 40 lectures plus some tutorials, marking and examining. Fee £700 for each course. Apply to Professor W. B. Bonnor or Departmental Secretary at Queen Elizabeth College, Campden Hill Road, London W8 7AH. Tel: 01-937 5411. 131(A)

**MOLECULAR BIOLOGY OF
ONCOGENIC VIRUSES
ASSISTANT OR
ASSOCIATE MEMBER**

The Division of Virology, St Jude Children's Research Hospital, invites applications from individuals with promise (assistant) or evidence (associate) of outstanding research abilities. We favour candidates with interests in nuclear DNA viruses (papova, adeno, herpes) and experience in recombinant DNA technology. However, exceptional candidates with other research interests will be considered. This is a full-time research position with no teaching or service responsibilities. St Jude Hospital is an equal opportunity employer. Please submit curriculum vitae, summary of research plans, and names of three referees to: Dr Allan Granoff, Chairman, Division of Virology, St Jude Children's Research Hospital, Memphis, TN 38101. W1(A)

**UNIVERSITY OF
DUNDEE
DEPARTMENT OF
BIOCHEMISTRY
POSTDOCTORAL
RESEARCH FELLOW**

Applications are invited for an M.R.C.-supported postdoctoral fellowship to continue highly-productive work on the perinatal triggering and development of enzymes, particularly those in the endoplasmic reticulum and concerned with drug metabolism. The successful applicant would join another Postdoctoral Fellow and a technical team utilising a wide range of techniques, including hormone assay and cell culture, but proved biochemical research ability and imagination are more important than experience in these particular techniques.

The appointment will be available from June 1, 1979 until September 30, 1981. Renewal for a subsequent period may prove possible. Salary within the range £3,883 to £6,555 (under review) with initial placing dependent on age, qualifications and experience. Further information is available from Professor G. J. Dutton.

Applications, quoting Reference EST/39/79K and containing full curriculum vitae and the names of two referees, should be lodged by April 16, 1979 with The Secretary, The University, Dundee DD1 4HN. 135(E)

**UNIVERSITY OF
SOUTHAMPTON
SCHOOL OF BIOCHEMICAL
AND PHYSIOLOGICAL
SCIENCES
POSTDOCTORAL
RESEARCH FELLOWSHIP
PHYSIOLOGY/
PHARMACOLOGY**

Applications are invited for a POSTDOCTORAL RESEARCH FELLOWSHIP IN PHYSIOLOGY. Candidates should have a scientific and/or medical qualification and research experience, preferably with publications, in an aspect of Physiology and/or Pharmacology. It would be helpful if the applicant had particular interest in cardiovascular and/or renal physiology and in the mechanism of action of angiotensin. The successful applicant will join research teams actively involved in transport studies renal physiology and hypertension and/or studies into the physiological effect of burns. The Research Fellow may be called upon to participate in research supervision and from time to time in a small amount of teaching of courses in both the Faculty of Science and in the Faculty of Medicine. Excellent facilities for research in all aspects of physiology, pharmacology, histology and histochemistry are available. The appointment is for one year in the first instance, is renewable and will commence as soon as possible. Further particulars are obtainable from Professor K. A. Munday.

Salary Range: £3,883 to £4,882 per annum (under review). USS benefits. Initial placing according to qualifications and experience. Applications giving date of birth, curriculum vitae and the names and addresses of three referees, should be sent by April 20, 1979 to: Mrs P. Vaughan-Smith, The University, Southampton SO9 5NH, quoting reference 1061/R. 162(E)

COURSES

**University of London
ROYAL POSTGRADUATE MEDICAL SCHOOL
ADVANCES IN IMMUNOLOGY
14-18 MAY 1979**

Recent Advances in Immunology will be presented in small symposia, by experts in their particular fields, followed by panel discussions. There will also be presentations of clinical material and current research at the Royal Postgraduate Medical School. The course is intended for those who already have a background in Immunology and will be of interest to both clinicians and to non-clinical immunologists.

Contributors include:

Professor J. R. Batchelor	Dr. M. J. Crumpton
Professor A. J. S. Davies	Dr. A. Feinstein
Dr. S. Gordon	Dr. G. R. V. Hughes
Professor J. H. Humphrey	Dr. A. B. Kay
Dr. G. G. B. Klaus	Professor P. J. Lachmann
Dr. W. E. Parish	Professor J. Pepys
Dr. M. B. Pepys	Professor D. K. Peters
Dr. M. C. Raff	Professor I. M. Roitt
Professor J. Soothill	Dr. C. J. F. Spry
Dr. M. J. Taussig	

Special Guest Lecturer: Professor R. R. Porter

Course fee: £90 (including catering)

Course organisers: Dr. M. B. Pepys and Dr. C. J. F. Spry

Application forms available from:

The School Office (SSC)
Royal Postgraduate Medical School,
Hammersmith Hospital,
Du Cane Road,
London W12 0HS.
Telephone: 01-743 2030 ext 351

130(D)

**THE ANIMAL
HEALTH TRUST
WOOLDRIDGE FARM
LIVESTOCK FELLOWSHIPS**

Applications are invited from veterinarians and scientists with postgraduate research experience who will design and undertake studies of the major factors influencing the health and productivity of cattle, sheep and pigs.

The fellowships are tenable for up to three years at an agreed place of work commencing October 1, 1979.

Stipends, depending on age and experience, are within the range £3,500 to £5,000 per annum. A reasonable sum will be allowed for approved expenditure.

Applications which must be sponsored by the head of the department in which the candidate proposes to work, should include the candidate's formal curriculum vitae, full details of the proposed research programme, and the names and addresses of three referees.

Further details and application forms are obtainable from the Director, The Animal Health Trust, Lanwades Hall, Kennett, Nr. Newmarket, Suffolk CB8 7PN. Closing date April 20, 1979. 121(E)

**UNIVERSITY OF
NOTTINGHAM
DEPARTMENT OF CHEMISTRY
TEACHING FELLOW IN
INORGANIC CHEMISTRY**

Applications are invited for a University Teaching Fellowship from candidates who have recently obtained, or expect shortly to obtain, a Ph.D. degree. The person appointed will be required to help with the teaching of Inorganic Chemistry and will also be expected to join a research group with Professor J. J. Turner and Dr M. Poliakoff working in the areas of laser photochemistry and matrix isolation of inorganic species.

The appointment will be for three years and within the salary range £3,883 to £4,631 p.a. (under review).

Further information can be obtained from Professor Turner (Department of Chemistry); applications enclosing a curriculum vitae and the names of two referees should be sent to the Staff Appointment Officer, University of Nottingham, University Park, Nottingham NG7 2RD. 163(E)

FELLOWSHIPS

**UNIVERSITY OF
ABERDEEN
DEPARTMENT OF
MICROBIOLOGY
POSTDOCTORAL
RESEARCH FELLOWSHIP**

Applications are invited for an S.R.C. Research Fellowship working with Dr W. A. Hamilton and Dr I. R. Booth on the role of ion transport systems in energy transduction in bacteria.

Appointment will be from October 1, 1979 and will be for one year in the first instance with possible extension up to a maximum of three years.

Salary within Range 1A, £3,883 to £4,631 per annum, with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (two copies) should be lodged by April 13, 1979. 117(E)

**UNIVERSITY OF
ABERDEEN
DEPARTMENT OF BIO-MEDICAL
PHYSICS AND BIO-ENGINEERING
Summer School in Medical
Physics for Schools'
Physics Teachers**

From 20-24 August, 1979, the above Department will be running a Summer School in Medical Physics to show how current ideas and practices in medical physics may be used to illustrate fundamental principles.

The course is intended primarily for schools' sixth form physics teachers but is also open to members of other educational establishments.

Further details and application forms from the Course Organiser, Dr P. P. Dendy, Department of Bio-Medical Physics and Bio-Engineering, Foresterhill, Aberdeen. 151(D)

**UNIVERSITY OF
THE WITWATERSRAND,
Johannesburg, South Africa
SOLID STATE PHYSICS
RESEARCH UNIT
SENIOR
RESEARCH FELLOW/
RESEARCH FELLOW**

Applications are invited for appointment to the above two posts. Duties are to be assumed on a date to be negotiated.

Research Fellowships carry very light teaching responsibilities, an appointments are normally for a period of two to three years, although short-term contracts may be considered. The interests of the Unit include low temperature physics, E.S.R., N.M.R., X-ray diffraction, optical and other studies of defects in solids and theoretical solid state physics.

The salary ranges are:

Senior Research Fellow:

R10,144 to R13,489 per annum

Research Fellow:

R7,554 to R11,007 per annum

A salary review is expected in April 1979.

The initial salaries for both posts will be determined according to the qualifications and experience of the appointees. A grant towards removal expenses is normally made.

The University's policy is not to discriminate in the appointment of staff or the selection of students on the grounds of sex, race, religion or colour. Further particulars relating to this practice and to the above posts are included in an information sheet obtainable from the London Representative, University of the Witwatersrand, Chichester House, 27 High Holborn, London WC1V 7HE, or from the Registrar, University of the Witwatersrand, Jan Smuts Avenue Johannesburg, 2001 South Africa, with whom applications should be lodged by April 12, 1979. 127(E)

FELLOWSHIPS—continued

UNIVERSITY OF
DUNDEE

Candidates with appropriate post-graduate qualifications in Biochemistry are invited to apply for appointment to a

POSTDOCTORAL

RESEARCH FELLOWSHIP

to work with Dr J. L. Young (Dept. of Obstetrics and Gynaecology) and Dr D. A. Stansfield (Dept. of Biochemistry) on a M.R.C.-funded study of the hormone receptor/adenylate cyclase complex of the corpus luteum.

The appointee will be based in the Department of Obstetrics and Gynaecology at Ninewells Hospital and Medical School, Dundee, but close co-operation with the Department of Biochemistry will be maintained.

The appointment is available for approximately three years. The initial salary will be dependent of qualifications and experience but within the range £3,883 to £6,555.

Applications in writing, quoting Reference EST/41/79J and containing the names of two referees, should be lodged as soon as possible with The Secretary, The University, Dundee DD1 4HN. 134(E)

UNIVERSITY OF
ABERDEENDEPARTMENT OF CHEMISTRY
POSTDOCTORAL
RESEARCH FELLOWSHIP

Applications are invited for an R.C. Research Fellowship working with Dr A. R. West on novel, solid state energy storage systems.

Appointment will be from April 1, 1979, or as soon thereafter as possible, and will be tenable for two years. Commencing salary within Range 1, £3,883 to £4,382 per annum, with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen with whom applications (2 copies) should be lodged by April 27, 1979. 136(E)

THE UNIVERSITY
OF SUSSEX
SCHOOL OF MOLECULAR
SCIENCES

RESEARCH FELLOWSHIPS

Two Research Fellowships available for up to three years' research on M.R.C. projects related to the mechanism of action of metallo-enzymes. Ph.D. in chemistry or biochemistry required with experience in one or more of the following fields: e.p.r. of free radicals or transition metals; molybdenum chemistry; enzyme mechanisms or enzyme isolation; cryobiochemistry; fast reactions. Salary on the scale £3,883 to £6,555 p.a. (under review) with superannuation benefits. Open to men and women. Full details of experience and the names of two referees should be sent to Dr R. C. Bray, School of Molecular Sciences, University of Sussex, Falmer, Brighton, BN1 9QJ. 105(E)

RESEARCH FELLOWSHIP
INSTITUTE OF CELL
BIOLOGY

Swiss Federal Institute of
Technology (ETH)
Zürich—Switzerland

A
POSTDOCTORAL FELLOW

is required from August 1, 1979 to join a group working on structural aspects of chromatin and DNA using biophysical (electron microscopy, laser light scattering) and biochemical techniques. Experience in molecular biology or physico-chemistry of macromolecules desirable.

Salary in accordance with age and experience on ETH Grade I (Sfr. 41'600.— to 48'900.—).

Enquiries or applications with curriculum vitae and names of two referees to:

Dr Th. Koller,
Institute for Cell Biology,
ETH-Hönggerberg,
CH-8093 Zürich,
Switzerland. W18(E)

THE QUEEN'S
UNIVERSITY OF BELFAST
ROBERT W. WALLACE
MEMORIAL
STUDENTSHIP

This Studentship is open to graduates in Agriculture, Agricultural Science or Science for research in the Department of Mycology and Plant Pathology of the Faculty of Agriculture and Food Science on gangrene and related tuber diseases of potatoes. The holder will be required to study for a higher degree of the University. The value of the Studentship, which is tenable for three years from October 1979, is £1,650 p.a. (subject to review), plus fees and a sum of up to £150 per annum will be available for travelling and other expenses.

Candidates should apply to the Dean, Faculty of Agriculture and Food Science, Newforge Lane, Belfast, BT9 5PX, for an application form which should be returned by April 27, 1979. 155(F)

EDINBURGH
UNIVERSITY
SCIENCE STUDIES
UNITPostgraduate
Studentships

available for research in social and historical aspects of science and technology, including Appropriate Technology for the Third World. Further details from: Secretary, Science Studies Unit, 34 Buccleuch Place, Edinburgh EH8 9JT. 142(F)

THE UNIVERSITY
OF MANCHESTER

Applications are invited from graduates or those expecting to graduate in 1979 for:

RESEARCH STUDENTSHIP
IN SCIENCE AND MEDICINE

Value as for S.R.C. studentships, renewable after first year.

Particulars and application forms (returnable by June 1) from the Registrar, The University, Manchester M13 9PL. Quote ref: 55/79/N. 108(F)

AWARDS

IMPERIAL COLLEGE
London, S.W.7

S.R.C. C.A.S.E. AWARD

Applications are invited for an S.R.C. C.A.S.E. Studentship to investigate Combustion in Heat-recirculating Burners.

Candidates should be graduates, or expecting to graduate in 1979, with a good honours degree. The research project, concerned with pollution-free burning of poor fuels and lean mixtures in spouted beds and heat exchangers, will be carried out in collaboration with the British Petroleum Research Centre at Sunbury.

In addition to the standard S.R.C. rates (currently £1,990 per annum) the bursary will include a financial contribution from British Petroleum Limited. Additional allowances apply in the case of married students and those with industrial experience.

The successful candidate will be expected to proceed to the Ph.D. and D.I.C. degrees.

Applications, including the names of two referees, should be sent as soon as possible to Professor F. J. Weinberg, Department of Chemical Engineering and Chemical Technology, Imperial College, Prince Consort Road, London SW7 2BY. 133(N)

GRANTS & SCHOLARSHIPS

THE ANIMAL
HEALTH TRUST
RESEARCH TRAINING
SCHOLARSHIPS

Scholarships for veterinary or science graduates who are under 30 years of age and wish to pursue a veterinary research career.

Value £1,500 per annum plus a reasonable contribution towards essential fees.

Tenable at appropriate U.K. institutions for up to three years.

Applications which must be sponsored by the head of the department in which the candidate proposes to work, should include the candidate's formal curriculum vitae, full details of the proposed research programme, and the names and addresses of three referees.

Further details and application forms are obtainable from the Director, The Animal Health Trust, Lanwades Hall, Kennett, Nr. Newmarket, Suffolk CB8 7PN. Closing date April 20, 1979. 120(H)

ASSISTANTSHIPS

UNIVERSITY COLLEGE
LONDONDEPARTMENT OF CHEMISTRY
POSTDOCTORAL RESEARCH
ASSISTANT

Applications are invited for a post-doctoral research assistantship tenable from about October 1, 1979, for one year with the possibility of extension for a second year.

Initial salary in range £3,909 to £4,408 (under review) depending on age and experience, plus £450 London Allowance. The research assistant will work with Professor F. Sondheimer on the synthesis of nonbenzenoid aromatic compounds and related substances.

Applications (one copy) with a brief curriculum vitae and names and addresses of two referees should be sent as soon as possible to Professor F. Sondheimer, Chemistry Department, University College London, 20 Gordon Street, London WC1H 0AJ. 173(P)

UNIVERSITY COLLEGE
LONDONDEPARTMENT OF PHYSICS
AND ASTRONOMYApplications are invited for a
POSTDOCTORAL RESEARCH
ASSISTANTSHIP

tenable for up to two years from October 1, 1979. This is funded as part of an S.R.C. grant for theoretical research on Interactions of Hadrons, Nuclei and Quarks.

Initial salary will normally be in the range £3,909 to £4,408 plus £450 London Allowance and the post carries U.S.S. benefits.

Applicants are requested to send curriculum vitae including list of publications, and also to arrange for three references to be sent direct to Professor L. Castillejo, Department of Physics and Astronomy, University College London, Gower Street, London WC1E 6BT. 178(P)

SEMINARS & SYMPOSIA

THE 27th SYMPOSIUM OF VERTEBRATE PALAEONTOLOGY AND COMPARATIVE ANATOMY is to be held at Oxford from September 24 to September 28, 1979. Anyone wishing to attend may obtain further particulars and a booking form from Dr T. S. Kemp, University Museum, Parks Road, Oxford OX1 3PW. 139(M)

September 23-29, 1979. International Symposium on E.S.R. in Chemistry. Thessaloniki (Prof. A. Anagnostopoulos, Inorganic Chemistry Laboratory, School of Chemical Engineering, Faculty of Technology, Aristotle University of Thessaloniki, Greece). W13(M)

CONFERENCES

AN INTERNATIONAL CONFERENCE ON
CELL PROLIFERATION IN THE
GASTROINTESTINAL TRACT

Will be held in Newcastle upon Tyne, England
on September 10, 11 and 12, 1979

Speakers include: N. A. Wright, R. P. C. Rijke,
R. F. Hagemann, C. S. Potten, J. P. Sunter and M. Lipkin

Contributions are invited.

Further particulars may be obtained from Dr D. R. Appleton,
Department of Medical Statistics, University of Newcastle
upon Tyne, NE2 4AA, England. 153(C)

STUDENTSHIPS

MEDICAL RESEARCH COUNCIL

Clinical and Population Cytogenetics Unit

Applications are invited for graduates with good honours degrees and from prospective graduates for

MRC RESEARCH STUDENTSHIPS

that have been requested for October 1979. Awards will be in the fields of meiosis immunoglobulin production *in vitro* and computer pattern recognition. Studentship will be for a maximum period of 3 years and successful applicants will be expected to register for the degree of Ph.D. at the University of Edinburgh.

the Administrative Officer, MRC Clinical and Population Cytogenetics Unit, Western General Hospital, Crewe Road, Edinburgh EH4 2XU. 174(F)

Why is a beautiful
hotel like the Pulitzer
featured in a
magazine like this?

Guess!

Even a scientist needs to relax

The four star Pulitzer is located along one of Amsterdam's most famous canals in the heart of the city. 17 historic buildings were completely restored to their original beauty and combined to house 175 guest rooms all with modern facilities. Graced with beams and natural brick walls, each room reflects a rustic charm not found elsewhere in Amsterdam.

You'll find a cozy bar to relax after a busy day. A restaurant which serves delicious Dutch and French food. And keep in mind that the Pulitzer has private meeting facilities up to 60 persons.

So when you're planning a trip to Amsterdam, remember the Pulitzer.

For additional information and instant free reservations: Call Nicholas Lawson Ltd. London: 01/4917431, telex 23189.

IMMUNOCHEMICALS FROM MILES?

YES, INNOVATIVE AND PROVEN PRODUCTS FOR RESEARCH AND CLINICAL LABORATORY USE.

Perhaps you think of Miles as a place to get the unusual, like antiserum to rat IgE or equine IgM.

Perhaps you know we offer a wide selection of human protein antisera encompassing newer products, such as antisera to myoglobin, ferritin and β -2 microglobulin, as well as established antisera to immunoglobulins, α -1 antitrypsin and other major serum proteins.

Of course, you may not associate us with immunochemicals at all... We think you should.

We're all using it!

PharmalyteTM, the new ampholyte

Pharmalyte is part of a new integrated system for flat bed isoelectric focusing, electrophoresis and immunoelectrophoresis. Find out more about Pharmalyte and the Pharmacia Flat Bed System – today!

Pharmalyte gives you:

- Convenient and stable gradient intervals without mixing

- More resolution. Over 1000 high buffering capacity ampholytes per pH interval

- Less risk of local "hot-spots" and overheating because the conductivity is even across the whole gradient

- Easier recovery of proteins. Pharmalyte doesn't contain high molecular weight contaminants.

Pharmalyte is a series of new and unique carrier ampholytes developed entirely within the research laboratories of Pharmacia Fine Chemicals to give you superior resolution in isoelectric focusing.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; $\exp(a)$ is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish. *Nature's* publishing policy is outlined in 258,1 (1975) and 264, v, 11 Nov. (1976).

FASEB exhibition news

When you're studying cyclic nucleotides and you don't know which way to turn

We understand that when you are working in the cyclic nucleotide area, the subject is so diverse and so complex that you don't want to have to worry about the problems of accurate measurement.

So we would like to take a little weight off your mind and offer you our two kits in this field.

Cyclic AMP and Cyclic GMP.

Both of the tests are simple, accurate and will take you about four hours from start to finish.

So it's not surprising that you can carry on with your research and leave the problems of accurate measurement to us.

You know where you are with our Cyclic AMP & GMP kits

Recombinant DNA—how public?

A PROBLEM increasingly facing scientists is the pressure to become involved in public discussion of the assessment of risk. Although initial fears about potential health hazards of recombinant DNA research have proved to be exaggerated, the public discussion has required scientists to take a stand on the risks involved—just as public policy decision in other fields, such as the control of chemical carcinogens, has needed assessments that can be backed up by scientific data. In both instances there are two, related, requirements: the first is a reasonable interpretation of available data, and the second is that the public should have confidence in this interpretation.

Much thinking has, of course, been taking place on both sides of the Atlantic on how best to relate the scientific to the policy aspects of risk assessment (the need for which is now generally accepted even by those who continue to dispute whether such assessment can be reduced to cost/benefit analysis). Some have argued strongly for a clear separation of the scientific and regulatory aspects. The US National Academy of Sciences, for example, in a report on food additives published in Washington last month, suggested that it should be a scientific task to divide potentially harmful food additives into three categories of risk, and then a regulatory task to decide how substances in each category should be dealt with. And staff members of the President's Science Adviser's office have suggested a broadly similar, interagency approach to all areas of regulation of carcinogenic substances (page 388).

Such an approach has obvious attractions but in practice it is often difficult to draw the dividing line between the scientific and the political judgement. Frequently there is a lack of adequate scientific data to reach a firm conclusion on the subject under debate—the effects of low level radiation, or even the health hazards of recombinant DNA research, are two obvious examples. In such cases, a variety of interpretations can be compatible with such data as are available. And the choice between different interpretations is one that expresses social or political interests (those who wish to pursue a certain line of research, whether the nuclear industry or DNA research workers, will tend to favour the interpretations that minimise the hazards—their critics will tend to take the opposite view).

One should not be surprised at this situation, merely aware of the bias that will inevitably creep in. But one

thing that is certain is that to achieve a reasonable and acceptable policy position, the public debate on such risks must be as open as possible.

What then are we to make of the restrictive notice from the organising committee of the forthcoming international scientific meeting on recombinant DNA at Wye College, Kent, which puts the whole meeting 'off the record'? The purpose of the meeting, supported by ICSU and the Royal Society, is 'to review the current status of DNA research and technology, and to discuss matters of concern such as support for the research, its regulation through guidelines and legislation, and the eventual practical application of the technology'; widespread participation is called for. And yet participants have now been told that for 'free and frank discussion usual to scientific meetings' the proceedings will be strictly off the record, and that everyone should respect the 'established convention of private communication between scientists, and not contribute to any reviews for publication other than . . . the official proceedings'. Originally the press was to be excluded entirely, but now three science writers will attend (from *Nature* and *New Scientist*) provided they refrain from recording the meeting, or writing reports for general publication directly from the proceedings.

Of course scientists working in this field may at times have felt hard done by the media. And of course it is open to journalists to get the material by the alternative route of dogged pursuit of participants for on-the-record comment. But the committee has already clearly set the tone—the discussions are too sensitive to be widely disseminated, except in an official version. Others may conclude—perhaps quite wrongly—that there are other things to hide.

Moreover, it is never possible for all those who wish to attend to find the time and money to do so. Sober reporting of the proceedings fulfils an important function of allowing the whole community, not just those able to get to a particular place, to gain at least some impression of what went on.

Science, we are continually reminded, is public knowledge, freely available. Anyone lecturing to a large audience accumulated by advertisement as well as by invitation participating in this tradition, not conforming to the established convention of private communication. They should think again.

'Safety' cabinets are not safe, says UK study

Some of the most popular makes of safety cabinet used for biological research in the UK have containment factors 1000 times lower than the new British Standard, writes **Judy Redfearn**.

WORK sponsored by the UK Medical Research Council has shown that the vast majority of 'safety' cabinets currently being used for microbiological work in hospitals, universities, and research establishments throughout the UK offer so little protection to those working with them that the term safety cabinet is a misnomer. An important and positive outcome of this work, however, has been the preparation of the first British Standard (BS 5726) for safety cabinets, which is due for publication "any time now". The standard will define three classes of cabinet (see figure) and recommend minimum containment levels for each.

The cabinets which are causing most concern have a linear downflow of air at the opening. Of the dozen or so makes of this type (class II) currently available in the UK, only two, the UK-manufactured Howarth and the Italian Gelaire, have been found to come up to the new BS recommendation for containment.

Some popular makes of cabinet to have containment factors up to 1,000 times less than the recommended minimum. According to Dr R. P. Clark of the Clinical Research Centre, Harrow who has done much of the work for the MRC, in some cases and for some uses a microbiological worker could be at greater risk when using a cabinet than when working on the open bench—because the air flow created by the cabinet could cause infectious material to be blown directly at his or her face.

Class II cabinets are very popular for work where total containment is not thought necessary, because they are had been thought to offer some protection both to the worker (from inhaling infectious particles) and to the work (from contamination from the environment). The latter can be important during work with tissue cultures.

The cabinets operate by drawing air through the front opening and down through a grille in the floor. The air

then moves behind the cabinet and through high efficiency filters before re-entering the cabinet through the roof. During normal operation, about 80-90% of the air is recirculated back into the cabinet and the remaining 10-20% is filtered and discharged to the atmosphere. Drs Clark and B. J. Mullan used Schlieren photography to look at the air flow in and around cabinets running with and without an operator. They also examined the effect on the air flow of a person walking past the front of the cabinet or of a door opening and closing near it, of talking or coughing towards the cabinet and of a lighted Bunsen burner inside it. Behaviour of the air flow was also examined after switching the cabinet off.

For all the cabinets tested they found that in the first 3s after switch-on a "large rolling eddy" of air spilled out of the front opening. The flow pattern then settled down and a substantial bulge of air began to circulate regularly outside the cabinet. Some air was convected away from the bulge to mingle generally with the air of the room.

The effect of an operator working with the cabinet was to cause turbulence in the air bulge outside. When a smoke pellet was ignited in the cabinet, smoke was clearly seen emerging through the front opening above the operator's hands and moving towards the face. The effect of someone coughing or speaking towards the cabinet or walking past the front of it, or of a door opening and closing near it, was to disturb the air bulge and cause it to mingle with the air in the room. After the air flow through the cabinet was switched off, the warm air inside moved upwards and outwards from the front opening and continued to do so for 10-20 min.

Drs Clark and Mullan have tried to quantify these disturbing observations by measuring the containment of various makes of cabinet. They created an aerosol of potassium iodide solution inside each one and measured the

number of droplets contained per unit volume of air just outside the front opening. They then performed the same experiment on the open bench and calculated the ratio of the measurement made on the open bench to that made with the cabinet.

This work is the basis of the new British standard. The standard will recommend that Class II cabinets (with a dummy arm inserted in the front opening) offer 10^5 times more protection to the operator than the open bench.

When tests first started at the Clinical Research Centre no UK-manufactured cabinets came up to this specification and some had containment factors of only 10^2 . In the light of this work, however, one UK manufacturer has designed a new cabinet, the Howarth, which meets the BS specification. The cost of this model compares well, according to Dr Clark, with the cost of other less adequate cabinets. However it is disturbing, says Dr Clark, that some manufacturers are now rushing to sell off their old stock. He is aware of two firms taking orders in the last two weeks and threatening cancellation charges if the orders are withdrawn when the standard is announced.

But if—against this trend—the publication of BS 5726 goes hand in hand with a willingness of other manufacturers to substitute better designs, then the biologists will at least have started to tackle their major safety problem. Fume cupboards for chemical work, however, are likely to remain without a British Standard for some years yet. □

Figure: cabinets in Class I (left) are designed to protect the worker but not the work. Those in Class II (second left) are for protecting both the worker and the work—as are those in Class III (centre). The latter are for work with highly infectious or pathogenic organisms where total containment is needed. Right: what happens when an operator disturbs the air curtain in Class II cabinet.

US drug companies push for changes in recombinant DNA guidelines

David Dickson reports that fears of industrial espionage are making drug companies reluctant to comply with rules covering genetic engineering research

US pharmaceutical manufacturers are challenging a key section of the National Institutes of Health's guidelines covering recombinant DNA research, claiming that compliance under present procedures could lead to the disclosure of proprietary information to potential competitors.

The section in question is that which specifies the conditions under which certain experiments can be exempted from a prohibition on research involving more than 10 litres of culture—a situation which many companies are rapidly approaching as recombinant DNA technology moves from the research to the production stage.

Under an interim procedure agreed by the NIH's Recombinant DNA Advisory Committee (RAC) last month, applications for such exemptions have to be circulated to all members of the committee, and approved by a three-person subcommittee, before they can be granted by the director of NIH, Dr Donald Fredrickson.

Although legal provisions exist covering what may or may not be divulged by RAC members as "special government employees", Dr Fredrickson has said that he cannot guarantee the complete confidentiality of information submitted to the RAC as part of this approval procedure.

On the other hand, regulations covering the use of recombinant DNA techniques in private industry which are currently being drawn up by the Food and Drug Administration—and which will provide statutory protection for proprietary information—are not at present scheduled to be on the statute book before February 1980.

In the interim, unless an alternative way is found of protecting such information, pharmaceutical companies and other groups pursuing recombinant DNA research who need to go beyond the 10-litre limit as a step towards full-scale production, but do not want to divulge too much information to a potential competitor, have been faced with some hard choices.

Some, such as the Berkeley-based Cetus Corporation which is required by local laws to observe the NIH guidelines, plan to hold back on any experiments for which providing full details to the NIH would, they feel, prejudice their proprietary rights.

In contrast, the San Francisco firm Genentech is planning to take what one pharmaceutical industry official calls a "calculated risk" in conducting scaled up experiments according to the technical criteria that have been laid down by NIH, but without seeking the NIH's formal approval (although NIH will be informed when such experiments take place).

"To get the full benefits of this technology out, it is important to go rapidly to volumes greater than 10 litres", Mr Robert A. Swanson, president of Genentech, told *Nature* last week. He added, however, that there was no mechanism for doing this through NIH at present "that would take into account the necessity to protect proprietary information".

(Eli Lilley, the pharmaceutical company which has entered an agreement with Genentech to develop techniques for producing insulin, has suggested to the FDA that its proposed regulations—which are likely to require companies to show that a product has been developed under the NIH guidelines—"should include provisions for exempting studies commenced prior to the effective date of the guidelines or regulations".)

Issues related to the confidentiality of information, although they have been heatedly debated over the past two years in Britain's Genetic Manipulation Advisory Group, have tended to remain on the sidelines within the US debate, where greater attention has been given to public concern about the potential health hazards of the research.

As the production of substances such as insulin, growth hormone and interferon using recombinant DNA techniques comes closer to reality, however, companies which have agreed to comply voluntarily with the NIH guidelines are becoming increasingly concerned about being required to divulge commercially valuable information.

"There are not many companies wanting to do so at the present time, but within the next year or two you will have a lot of companies wanting to scale-up their research. And how you deal with proprietary information in such circumstances is causing some concern", says Dr Herbert Weissbach of the Roche Institute of Molecular Biology.

Dr Donald Fredrickson, Director of the NIH: under pressure on confidentiality

These sentiments are echoed by Dr John Adams, vice-president of the Pharmaceutical Manufacturers Association in Washington. "We do not feel that the NIH guidelines in their current form adequately address the problems that we have with regard to protecting the confidentiality of information. The problem is that there is nothing in the statutes of NIH that covers trade secrets."

At the same time, however, trade union and public interest groups are arguing that the more recombinant DNA techniques become part of standard production techniques, the greater the potential for serious health effects—and hence the greater the need for information about the processes involved.

Under the terms of the guidelines published by NIH last December, experiments requiring more than 10 litres of culture are prohibited unless the recombinant DNA's are rigorously characterised and "the absence of harmful sequences established". In such cases, the guidelines state that the experiments can be authorised by the director of NIH "under procedures specified by the RAC".

Exactly what these procedures should be is now under debate. At a meeting of the advisory committee held in Bethesda last month, Dr William Gartland, head of the NIH's Office of Recombinant DNA Activities (ORDA) suggested that as an interim procedure, applications for scaled-up experiments should be reviewed by the chairperson and two other members of the RAC.

This group, he suggested, would recommend whether the request should be approved by ORDA or whether it required review by the full committee, in which case a subcommittee of the RAC would review the application prior to being passed to the full committee.

Various members of the committee objected to this procedure, claiming that all members of the full committee should be involved in the decision.

receive details of all applications for scale up. "Otherwise the sub-group could theoretically be given a blank cheque to pass experiments without reference to the full committee" says committee member Dr Karim Ahmed.

After a certain amount of debate, it was agreed that until the next meeting of the advisory committee in May, any application for experiments over 10 litres would be examined by a three-person subgroup, but would also be circulated to all members of the committee one week prior to the subgroup's meeting (so far no such application has been received by NIH).

The next RAC meeting will also consider the report of a subcommittee set up by chairperson Dr Jane Setlow on how the phrase "the absence of harmful sequences" should be interpreted. Some have argued that even an insulin producing gene might be described as potentially harmful, depending on where it was functioning; and Dr Setlow is keen to ensure a reasonable uniformity of interpretation between different institutional biohazard committees (IBCs), which are already required to make such judgments in certain circumstances.

The major question regarding procedure, however, is whether the pharmaceutical companies, if they are required by the FDA to comply with the NIH guidelines, are prepared to accept the proposed arrangements as adequate to protect proprietary information; and conversely whether an alternative arrangement more to their liking will be acceptable to all members—and in particular the "public interest" representatives—on the advisory committee.

Already at least one company has approached Dr Fredrickson to see if he could give his approval to certain scaled-up experiments without consulting the RAC. But Dr Fredrickson has informed them that, under his interpretation of the current guidelines, there is no way this can be done.

The pharmaceutical companies are now focusing attention on the form of regulations which the FDA is likely to bring in, following its announcement last December that it was proposing to require that any firm seeking approval of a product "requiring the use of recombinant DNA methods in its development or manufacture" demonstrate its compliance with the requirements of the NIH guidelines.

According to FDA Commissioner Dr Donald Kennedy, the agency is confident that it can find some way to protect proprietary information as it does now with other commercial products, even if this information has to be submitted to NIH for approval.

But the drug companies are not so confident, and indeed are challenging

whether the FDA has the right to regulate the process, in addition to the product, of research.

"It may be difficult to show that any particular research protocol involves a specific trade secret", says Dr C. W. Pettinga, executive vice president of Eli Lilly which has been saying for some time that the need to conduct experiments involving more than 10 litres of culture is imminent, and is keen to press ahead with its own insulin research. "Also it may be possible for a competitor to determine from a series of protocols the general thrust of research activity that in part or in whole might be valuable proprietary information."

In comments to the FDA which Dr Adams of the Pharmaceutical Manufacturer's Association says are broadly supported in the industry, Dr Pettinga warns that unless information can be submitted in confidence to the members of the RAC, there is the danger of the premature disclosure of a potentially patentable idea "which would almost certainly preclude patent protection in most foreign countries".

Scale-up a local problem

He suggests that authority to increase the 10-litre limit, in a manner consistent with appropriate containment standards, be given to local institutional biohazard committees (which would also be empowered to approve the utilisation of host-vector systems and research protocols for all except experiments requiring the highest level of containment).

In broader terms, Dr Pettinga, with the support of other members of the PMA, says that "the regulation of basic research by FDA is not desirable". And he suggests a mechanism should be developed for voluntary compliance with NIH guidelines, and that FDA should remain involved solely

with procedures regarding the safety and efficacy of drugs, and not the regulation of research.

How FDA and NIH respond to these recommendations remains to be seen. Already there are disagreements over what constitutes adequate protection of potentially valuable information. NIH, for example, has suggested that to defend proprietary rights, institutions should apply for a patent before submitting information to the RAC; the pharmaceutical companies have replied that in most cases this is unlikely to work, since a potentially patentable discovery will be based on work that requires registration and/or approval before it can be carried out.

All sides are agreed, however, that the current situation is unclear. "We are hoping that somewhere down the road the rules of the game will be clarified and that reason will prevail. At present it is total confusion as far as we are concerned", Mr Peter Farley, vice-president of Cetus, said last week.

"Within the year we will be very concerned about the precise scale-up requirements. We will then have to pick and choose on a case by case basis whether to disclose full information of our plans to the NIH; if we were doing something very clever, the details of which we did not want others to know about, then for the time being we would do nothing."

One issue to be decided is how much information would need to be divulged to the NIH before a certain experiment would be approved as safe. "The characterisation of the gene presents no problem at all, since we would want to do this for our own safety. But describing specifically what one has done or providing the justification for going to larger volumes could involve sensitive information" says Dr Joseph Grady, of Upjohn Co.

A further matter of concern is that if private companies find they are unable to operate with the desired secrecy under NIH guidelines, then they may carry out their research in other countries with less stringent requirements. Already some US corporations with interests in recombinant DNA research are supporting the activities of foreign companies.

Any attempt to exploit loopholes in current legislation, however, is not likely to be looked upon kindly by Congress, which last year held back from legislating on recombinant DNA research in the private sector largely on the basis of companies complying voluntarily with the NIH guidelines. No company has refused to comply with the technical aspects, covering for example biological and physical containment levels; but neither has any said that they can work with the complete guidelines as they now stand. □

"Be careful! This place may be bugged!"

Britain's shadow science minister believes in experts

With the present government in Britain under extreme pressure to call an election,

Robin McKie interviews the Conservative spokesman on science and education, who feels that the major research companies should be more open about the research they undertake.

But expert committees should be left to experts

Ask a group of working scientists to react to the name of Mark Carlisle and it is likely that their responses will include a fair number of vague and inaccurate replies. This may not be particularly surprising but one cannot avoid feeling there should be a little more interest and reaction to a man who could shortly become overall leader of Britain's science effort.

In a surprise Shadow Cabinet reshuffle late last year, UK Opposition leader Mrs Margaret Thatcher appointed Mr Carlisle Shadow Secretary of State for Education and Science—in place of the previous, ebullient incumbent, Norman St John Stevas. Of course, the move does not automatically guarantee him the post of Education and Science Secretary in the increasingly likely event of the Conservatives bringing down the present Labour Government—but one only has to look to the example of Mrs Thatcher who held the same Shadow Cabinet post in 1970 and was appointed Secretary after Ted Heath won the general election that year. And it would also be strange to appoint another person just as Mr Carlisle had achieved some understanding of the complexities of the job.

So it seems timely to focus attention on the views of this 50-year-old barrister who may shortly influence so much of Britain's science policy. However, perhaps not surprisingly, Mr Carlisle is still reluctant to commit himself to particular doctrines or attitudes, stressing frequently that he will be guided throughout by the professional scientists and the various research advisory bodies. It is a natural reaction of a man new to the science arena, although one can already discern a less piercing or forceful interest in particular scientific topics than that shown by the present Secretary Mrs Shirley Williams, who has occasionally revealed great interest in subjects of special public concern such as genetic engineering.

However, some attitudes do become clear. In particular, Mr Carlisle shows a keen concern that science must be more closely tailored to suit the needs of British industry. In educational terms, this is reflected in a desire to increase emphasis on sandwich courses,

part-time education and polytechnic training.

And he particularly believes that greater encouragement must be given to further education at non-advanced, technician levels to provide necessary skilled manpower. "I think that one can foresee for the universities a period of consolidation, rather than expansion, and that any shift within the whole of education must go to scientific education and education in practical skills beyond the age of 16".

"The polytechnics have tended to move away from their original design and become less areas of technical education and more areas of general education. I think we have got to put the emphasis back on training the engineers and scientists that industry needs", he stated.

Mr Carlisle also stresses that more encouragement must be given to industry to carry out its own research rather than rely on strong Government backing all the time. "The Conservative philosophy is that Government should get off industry's back and leave it enough money for expansion which will allow more research. This will come from improving the tax structure and economic atmosphere of the country".

But if he is keen to tie science more closely to industry, then Mr Carlisle is less willing to have interference in the actual work of scientists. For instance he is quite adamant in his opposition to lay or union representation in bodies such as the Dangerous Pathogens Advisory Group or even the Genetic Manipulation Advisory Group.

"These are advisory boards on highly technical subjects and have to advise Government. If you are deciding on the appropriate degree of safety for testing then it seems to me that this is an area only in which the qualified are able to speak with authority", he added.

Instead Mr Carlisle believes, rather naively it may seem, that public opinion—"the most vociferous lobby in the country"—provides the best form of surveillance of the scientists' activities. However, on the subject of the Press, the major shapers of public opinion, he is less enthusiastic. "The newspaper reporting of science is probably no worse than the newspaper reporting of

Mark Carlisle: opposes union representation on GMAG and DPAG

anything else. It is only the bad news that makes the headlines".

But he does maintain that there should be greater openness in allowing more reporting of scientific matters. "I am quite sure that the major research companies have nothing to be ashamed of and should always be willing to speak to people and make it clear that they have nothing to hide."

On the more vexed problem of staff stagnation and ageing populations at universities, Mr Carlisle—in keeping with most other public figures—offers little in the way of comfort or solutions for the future.

"I am conscious that there is a feeling among younger members of university departments that today an awful lot of them are waiting to fill dead men's shoes. That is the root cause of the feeling of frustration among younger university lecturers.

"Sadly I don't think there is any simple solution. However, I think we have to invite the University Grants Committee completely to review the whole situation, particularly the question of levels of senior staff, and also encourage the setting up of fellowships, like the present SRC initiatives, to take up some of the strain".

And it is to be hoped that these measures, and the others outlined by Mr Carlisle, will prove in some way to be effective—for in a very short period they could be put into rapid practice. When, and if, that happens, we can then perhaps expect a little more reaction to the name of Mark Carlisle.

US urged to centralise scientific assessment of cancer risks

A SINGLE scientific organisation responsible for identifying and characterising potential carcinogens across a range of government agencies has been recommended in a report prepared by the staff of the US Office of Science and Technology Policy.

Such an organisation, which it is suggested should be based on an expansion of the national toxicology programme established last year by the Department of Health, Education and Welfare, would have two main responsibilities: to identify those substances which pose a potential carcinogenic risk to humans, and to characterise in quantitative terms the nature of the risk and the degree of certainty of current estimates.

The report is part of an attempt by the administration to improve the scientific base of the regulatory process, a need which President Carter was expected to refer to briefly in a speech on regulatory principles which he was due to give this week.

Addressing a senate subcommittee last week, Dr Frank Press, the President's science adviser, said that one of the current needs in science policy was to carry out an analysis of the research base of the regulatory agencies to see if it was adequate. "If more resources are needed, I cannot think of a higher

priority area than this one," he said.

Responding to a number of recent issues, such as heated debates over occupational exposure levels for lead and air pollution standards, the OSTP report says that in order to help develop a uniform decision-making framework for controlling potential chemical carcinogens, it is necessary to start by distinguishing scientific from regulatory decisions.

The first stage would involve scientific data collection and analysis, with risks expressed in comparative and quantitative terms, while the second would reflect a complete cost benefit analysis, taking into consideration human, economic and social factors—including the societal distribution on benefits and costs.

Priority for scientific analysis should be given to chemicals for which cost-benefit analysis performed with existing data suggests that regulation be indicated, but leaves too much uncertainty to justify immediate action.

"Priority setting and coordination of testing ideally should be done by a single group with input from all relevant agencies," says the report, recommending this approach in contrast to one in which assessment would be assigned to various scientific organisations on an agency-by-agency basis. □

UK ministry gives green light to 2,4,5-T

A REVIEW of the herbicide 2,4,5-T was published by the Ministry of Agriculture, Fisheries and Food (MAFF) last week. The document compiled by the Ministry's advisory committee on pesticides outlined the reasons for the MAFF announcement in July 1978 that herbicides containing 2,4,5-T were safe "if used in the recommended way for the recommended purposes" and that approval had been given for their continued use in the UK.

This is the advisory committee's 8th review of 2,4,5-T since 1967 and it points out that the decision it reached was based on certain premises. These are that "in general the dose makes the poison", that there can never be "total proof of safety", that where reasonable doubt about the risk of a product exists the advisory committee's policy is to "err on the side of safety".

The review points out that it is the presence of the toxic contaminant 2,3,7,8-tetrachlorodibenzo-p-dioxin (dioxin)—a known teratogen and carcinogen—which is central to the concern over the safety of 2,4,5-T, some 3 tons of which are used annually in the UK—1/15 of the 1970 figure. Pure 2,4,5-T, the advisory committee

concludes, offers no hazard to users. And it adds that the dioxin itself would "ensure no hazard" if it was present in the trichlorophenol used to manufacture 2,4,5-T in quantities less than 0.1 ppm.

In arriving at its conclusions, the committee reviewed several major studies on the herbicide, including a New Zealand Department of Health Safety Report which could find no link between human birth defects and 2,4,5-T spraying; an Australian National Health and Medical Research Council report refuting that birth defects in the state of Queensland were associated with the presence of dioxin caused by burning sugar cane stubble sprayed with 2,4,5-T; a West German Federal Health Office statement and Review each approving the use of the herbicide in the Federal Republic; and reports from Vietnam that 2,4,5-T spraying caused an increase in the incidence of malformation in children, but which were inconclusive owing to the inevitable inadequacy of the data from a war zone.

The advisory committee points out, however, that decisions such as this one on 2,4,5-T are never final. □

MRC unit finds UK suicide rate falls

THE MRC Clinical Psychiatry Unit in Chichester has released the results of a major study showing that from 1962-1974 suicide rates in the UK have declined in all age groups except young women of age 15-24. Cautioning against simple interpretations, Jim Jenkins, co-author of the report said that an "entire constellation" of factors must be taken into account in the case of the female figures including family size, number of children and patterns of female employment.

The overall decline in suicide rate could be attributed to the increasing social cohesion in Great Britain in the face of a declining standard of living and increasing unemployment. Ironically, the MRC unit itself is slated for unemployment. Following the Medical Research Council's usual policy of closing units when their directors retire the Chichester Unit will be closed in 1982.

An MRC site visit three years ago found that "suicide research had no future" and a petition to the MRC with the support of the MRC's National Staff Side Committee failed to re-open the case. "We tried to get the MRC to look at their decision again," says Jenkins, "but we were given no scientific explanation why the unit should be closed." □

Misha Voikhanskii finally permitted to leave Leningrad

DR MARINA VOIKHANSKAYA, the former Leningrad psychiatrist, was forced to emigrate from the Soviet Union in 1975 after she had repeatedly refused to administer neuroleptic drugs to political "patients". Her nine-year-old son, Misha was to have followed her, but his promised emigration visa was withheld until a few days ago.

Since coming to the UK in 1975, Dr Voikhanskaya has been an active campaigner against political misuse of psychiatry in the USSR. In 1977 she addressed the Honolulu meeting of the World Psychiatric Association on this subject. Meanwhile as Misha grew up he too became interested in psychiatric abuse. In December 1976, it was he who notified campaigners abroad that activist Vladimir Borisov had been taken to a psychiatric hospital.

Dr Voikhanskaya told *Nature* this week that she felt sure that the long delay in Misha's visa was an act of reprisal against her for having spoken out against Soviet abuses of psychiatry. "It is only due to constant pressure from the scientific community and the public at large that the Soviet authorities have finally given way." □

AGE SPECIFIC DEATH RATES FROM DIARRHOEA

Place & year	Age specific death rates per 100,000	
	0-11 months	1-4 years
New York, 1900	5603	398.7
New York, 1961	45	2.4
Punjab, India, 1959	3446	312

(From Gordon et al, (1963),
Amer.J.Sci. 245 : 345)

A cure for a killer—but how to deliver it?

Millions of Third World children die of diarrhoea each year, although there is a simple cure available: oral rehydration. Discovered by scientists a decade ago, it has still not reached the people most in need. **Anil Agarwal** reports

THE possibility of oral rehydration has provided Third World health authorities with a very valuable breakthrough in the treatment of diarrhoeal diseases. Loss of fluids and electrolytic salts is the major complication in acute diarrhoeas, and if uncorrected, the continuing loss results in shock and eventually death. Until now rehydration has been possible only by administering fluids intravenously, as the small intestine loses its ability to absorb sodium during an attack of acute diarrhoea. Oral rehydration has now become feasible, however, with the observation that glucose absorption remains largely intact, and that sodium is carried along with it.

The application of this discovery—largely the result of work carried out at the Infectious Disease Hospital, Calcutta, the Cholera Research Laboratories, Dacca, Johns Hopkins University and the US Centre for Disease Control, Atlanta—now gives mothers the opportunity to treat their children suffering from diarrhoea themselves, by making a simple solution of glucose and electrolytic salts and feeding it to them.

Millions of deaths

Mothers no longer have to take their suffering children to health centres and hospitals tens of kilometres away, merely to seek the qualified nursing abilities required for intravenous treatment. For the majority of Third World mothers, who still do not have any reasonable access to health centres and hospitals, the necessity for intravenous treatment has really meant no treatment at all, and hence death for their children—a report from a research project situated in the relatively well-served region of Punjab, India, recently pointed out that though medical orders to village health workers called for children with clinical signs of dehydration to be immediately referred to the physician at the health centre, many children still died at

home of dehydration after they had been seen by the health worker. Many other children died without being seen at all. In this region, diarrhoeas were found to be responsible for 44% of all deaths amongst children less than three years of age. Considering that in many parts of the Third World, deaths amongst children constitute nearly half of all deaths in the population, the control of diarrhoeal diseases is of vital importance for the improvement of Third World health. It is estimated that there are some 500 million episodes of diarrhoea every year amongst children below the age of five. Experts differ, but it is widely accepted that these attacks result in the death of some 5-20 million children every year.

It is ironic that though diarrhoeal diseases have been reduced to a mere inconvenience in the developed countries, they still constitute the biggest cause of death and ill-health in the Third World. The primary cause of diarrhoeas is, of course, lack of clean water and generally insanitary conditions. But unfortunately these conditions are quite unlikely to change for at least another decade or two. WHO surveys show that as much as 78% of the Third World's rural population is still without clean community water supplies and about 85% is without adequate excreta disposal facilities.

Given these dismal conditions, oral rehydration has certainly opened up a glorious opportunity to take treatment, if not prevention, of diarrhoeal diseases to every doorstep in the Third World, however remote it might be, and control their worst consequences, dehydration and shock. In fact, oral rehydration can render an even more valuable service by helping to overcome the debilitation caused by the overwhelming majority of diarrhoeal attacks, which are mild and moderate, and do not lead to acute complications like dehydration. Together with mal-

nutrition, these diarrhoeas combine to form a vicious, mutually reinforcing complex of disease and ill-health. Malnutrition increases susceptibility to diarrhoeal attacks and persistent diarrhoeas increase malnutrition. If a child somehow survives the combined influence of these two, then a minor disease like measles often proves sufficient to kill him. However, studies now show that a child regularly treated with oral fluids should be able to maintain relatively good health. Trials in the Philippines for seven months, and in Turkey for 16, revealed that children who were given oral fluids had much higher monthly weight gains than those children who were left untreated: the mean weight gain of the non-treated children was significantly below that of the average growth curve.

Tests

The first serious test of oral rehydration took place in 1971 when cholera epidemics were taking a heavy toll of millions of Bangladeshi refugees who had poured into India. Two or three physicians, assisted mainly by the illiterate family members of the patients, were able to treat with oral fluids 3,700 severely ill refugees in less than two months. It was a state of total confusion, with up to 200 new patients being admitted daily; even space on the mud floor was full of purging patients. But only 125 patients (3.6%) died—and half of these before they could be given any fluids. By contrast, 9% of cholera cases in Italian hospitals died in 1973.

WHO and UNICEF are now spear-

Above: left, the death rate tells its own story. Right, the malnourishment of this child obscures diagnosis. The combination of symptoms is not rare in cases of diarrhoea, where repeated attacks worsen the condition. The majority of cases occur within the age group 6 to 18 months.

Measuring bottles and clean glassware are available in hospitals, as here in Papua New Guinea, but not in villages.

heading an international campaign to persuade Third World governments to introduce oral rehydration work in their primary health care activities. Numerous WHO-sponsored field studies are in progress, or have been completed in Egypt, El Salvador, Guatemala, India, Iran, the Lao People's Democratic Republic, Liberia, Nigeria, Turkey and the Philippines. Through these studies, WHO hopes it will be possible to convince local health administrators of the practicability and benefits of the new method. Many Third World hospitals have already adopted oral rehydration. The great majority of cholera patients at the Infectious Diseases Hospital in Calcutta, for instance, are now being treated in this way. The switchover from intravenous to oral fluids has meant a saving of about 50,000 dollars every year for the hospital in the cost of the fluids alone. More than a third of the beds in children's hospitals and wards in developing countries are usually occupied by diarrhoea cases receiving expensive antibiotics and intravenous fluids, thus putting a heavy load on their limited budgets. These units will greatly benefit from oral rehydration.

Delivery

Exactly how this new revolutionary therapy should be delivered to the Third World's million villages is, however, a matter of controversy amongst child health experts. WHO believes that the ideal course of action, in the interest of standardisation and quality control, is to prepare packets of oral rehydration salts in a standard mixture (3.5 g sodium chloride, 2.5 g sodium bicarbonate, 1.5 g potassium chloride and 20 g glucose) that would make a litre solution, and then sell these packets widely through commercial channels or distribute them through rural health centres. UNICEF is helping developing countries not only to distribute these packets but also to set up units to produce them. The packet approach is gaining acceptance. UNICEF has already distributed more than a million packets in developing countries, while Royal Drugs Ltd in Nepal has marketed over a quarter of

a million packets through commercial channels in the Kathmandu Valley. Since 1974, Indonesia has been running a national rehydration campaign with provision of locally packaged glucose-electrolyte mixture to its more than 2,000 rural health centres, and large numbers of commercial firms also retail the packets in the open market place. Costa Rica has instituted a national programme using packaged solutions, with the help of the Pan-American Health Organisation. The Cholera Research Centre in India has launched a drive to popularise oral fluid therapy among doctors and the lay public. Under contract from the Indian Council of Medical Research, a reputable drug firm has been entrusted with the large-scale production of oral rehydration packets.

WHO's "appropriate technology for health" programme is simultaneously trying to find cheap and simple packaging methods, in the interest of the poorer consumers: packaging constitutes as much as 50-75% of the price of producing a pre-packaged mixture. Machine-packaging is one possibility, using a vacuum sealed aluminium packet, coated with a plastic membrane inside. This type of packaging would minimise the moisture content, thus increasing the shelf-life of the powder. The price of a 1-litre machine-packaged UNICEF packet is currently estimated at 6.5 US cents. Hand-packaging would be cheaper and would create more employment, though the shelf-life of the powder would be less. In many rural areas of the Third World there already exist small packaging workshops where household articles and some drugs are packaged into polythene bags, and such workshops would be ideal for the hand-packaging of glucose-electrolyte mixtures. The cost of such mixtures is estimated to be about 5 US cents. All the ingredients could be put together in one polythene packet, or, because hand-packaging retains some moisture, the salts could be packaged separately and then added to a packet containing glucose. The cost of the latter technique would be higher, but the shelf-life would be increased.

The major advantage of pre-packaged solutions is that mothers would get the quantity of each ingredient correctly measured. An excess of potassium salts can be toxic. Large excess quantities of sodium can cause hypernatraemia, a condition that affects the heart.

Critics

There are, however, several critics of the WHO-UNICEF approach. Their arguments are largely based on the grounds that this approach has not adequately taken into account the extent of poverty of a large percentage

of the rural population and on the logistic difficulties of distributing centrally-produced packets to every village in the Third World. Packaging, which only adds to costs, can make even this simple and cheap oral rehydration therapy virtually prohibitive for millions of mothers. Distribution through commercial channels increases the price further by adding profits for manufacturers, distributors and retailers. Although these packets will eventually be required in hundreds of millions, manufacturers have not leaped into production, because, it seems, of the low profits at which they would have to sell them to reach the mass of the consumers. Distribution through health centres would also not reach the majority of the Third World rural population. In Indonesia, for instance, it has been estimated that distribution of packets through health centres has reduced mortality to less than 5% in dehydrated children, but only 10% of the total cases actually use health centres.

Another problem with the WHO standard 1-litre solution is that in most villages of the Third World mothers will not find it easy to measure a litre. Instead, every culture has some standard measure, based on a readily available container: in India, for instance, a 300 ml beer bottle can be found almost everywhere. But packaging in smaller quantities will only increase the cost of packaging, and hence the total cost of treatment. Moreover, keeping a litre of aqueous solution

This simple measuring spoon was developed for home use in Indonesia.

containing glucose for more than a few hours is not advisable in unhygienic rural conditions, as it would provide an excellent culture for several pathogenic organisms. Instead, it would be better to make the solution every time it is needed.

Mother the focus

The alternative approach being suggested is to make the mother the focus of oral rehydration treatment—to enable her to make and administer the solutions herself. Jon Rohde, who is working with a Rockefeller Foundation project on oral rehydration in Indonesia, argues that dehydration is just a form of malnutrition: fluid-electrolyte malnutrition. The key role of the mother in the treatment of

protein-calorie malnutrition is widely accepted. "Her role in replacing fluid and electrolytes is just as crucial," says Rohde. "perhaps more so considering the acute course of fluid-electrolyte malnutrition."

To enable the mother to treat her child herself, the WHO standard mixture can be considerably simplified. One problem is the availability of glucose, which has to be imported by most developing countries. Rural mothers will find it very difficult to obtain it. Glucose could therefore be replaced by the easily available white sugar (sucrose) which breaks down to glucose in the intestine. Sugar-salt solutions have indeed been tested by several researchers and have been found to be almost as effective as the WHO standard mixture in helping acute diarrhoea patients to recover. The simplicity of the sugar-salt solutions makes it possible for virtually every mother to become self-reliant. If nothing else is available, Dr William Cuttings of the London School of Hygiene and Tropical Medicine even recommends that mothers would do very well to use brown sugar or honey, which is available in many rural areas where beekeeping is a traditional practice. For potassium a mother could possibly squeeze in some orange or any other citrus fruit.

Researchers at the Institute of Child Health, Lagos, have found that poor mothers adopt the sugar-salt solution with great alacrity. All the

Fingers alone can measure quantities roughly. Left, 1.5 g, right, 30 g.

women attending the Institute's clinic are being taught oral rehydration therapy. In a recent survey, even women expecting their first child and others who had never used the service were able to describe the treatment. The survey however revealed that nearly half of the 217 women interviewed were planning to use more than four times the quantity of salt suggested to them (one-quarter teaspoon in a standard local beer bottle filled with water) and three cases were going to use sixteen times as much. Even very educated Western mothers have the tendency to believe that if something is good, more of it is even better.

To solve the problem of accurate measurement, a special plastic spoon has been developed in Indonesia which

has two separate indentations for measuring salt and sugar. This plastic spoon costs just 0.5 US cents. Such spoons are not only cheap, they could easily be made to suit local measures. Jon Rohde is using these spoons to teach children in primary schools and groups of mothers to make sugar-salt solutions. Dr Zafarullah Choudhury, a leading primary health care innovator from Bangladesh, is also teaching schoolchildren to make their own solutions. Because of its simplicity, Rohde strongly argues oral rehydration should be made everybody's business: "Teachers, agriculture extension workers, government employees, boy scouts, women's groups and even schoolchildren should be taught to mix rehydration fluids and use them."

No global method

Dr Christopher Lomax of the London-based Appropriate Health Resources and Technologies Action Group argues that "as in most 'appropriate technologies' it is difficult to recommend a single method to be used on a global scale, for each method will be viewed from a different perspective in different parts of the world".

Dr David Morley of the Institute of Child Health, London, who also strongly supports the use of spoons for measuring, believes that it would be best if national oral rehydration programmes were designed to operate at different levels of sophistication. At the level of the health centre, where even seriously dehydrated cases can be expected to turn up, both oral and intravenous therapy should be provided using the WHO standard mixture. But at the level of the individual mother, who has to treat most of the time mild and moderate diarrhoea cases, health authorities should promote the use of simple sugar-salt solutions made with the help of spoons.

WHO's Director-General, Halfdan Mahler, has in his speeches favoured the mother-based approach as best both in the long and short term. For WHO's new community-based approach to primary health care to succeed, Mahler has argued that a demystification of medical technology is needed. Oral rehydration, he believes, is an extremely good example where the responsibility of the community's health can be put into the hands of the community itself.

Maintaining standards

WHO's officials, however, who are very conscious of the organisation's reputation for medical standards, find it necessary to be cautious. WHO does not oppose any studies to test the efficacy of home-made sugar and salt solutions. But as all the major studies that have been published to date on the

The trend to bottle-feeding among the urban poor increases risk. Poverty means the mixtures are over-dilute, leading to malnourishment, and sterilisation of the bottles is impossible.

efficacy of oral rehydration have used the complete formula, WHO is making all attempts to promote widespread distribution of packets containing the standard mixture. It is felt that with sufficient education by health auxiliaries the complete formula can be mixed by mothers at home. With recurrent use of this solution, less education would be needed, and therefore hopefully there will soon be a minimum need for home-made sugar-salt solutions.

Dr Richard Cash of Harvard University also opposes attempts to simplify the oral rehydration therapy too fast. He believes that the medical community should not be bypassed. It is possible to go to the people directly and teach them self-help, but local doctors too must be adequately convinced of the effectiveness of a therapy before it is widely promoted. Otherwise, they will only discourage people from using them.

Furthermore, Dr Cash argues, the real problems in reaching the people is not scientific—whether one solution should be used or another—but lack of political will. It has taken ten years for governments to wake up to the possibility of oral rehydration since it was first indicated by scientific research. Producing packets and selling them is a far simpler job than undertaking a massive programme to educate every mother about oral rehydration. Governments, which still have to pick up the courage to provide more than half their population with adequate health services, are more likely to adopt the easier alternative.

The debate about oral rehydration does show that it is often easier to generate new medical knowledge that meets the needs of the neglected, underserved poor of the world, than it is to find ways to enable them to benefit from that knowledge. The debate about the delivery of oral rehydration parallels virtually every issue that has been raised in the more general primary health care debate about delivering health services to the rural Third World.

news in brief

France and Germany launch millimetre radio telescope project: The final go-ahead of the joint Franco-German millimetre radio telescope project was announced by Dr Kjell Johnson at the Rome meeting of the European Physical Society on 26 March. Conceived in 1973 the project was approved by the Centre National de la Recherche Scientifique (CNRS) and the Max-Planck-Gesellschaft zur Förderung der Wissenschaften (MPG) at the end of last year. CNRS and MPG will share the initial construction expenses of 160mFF equally with much of the MPG contribution coming from the Volkswagen Foundation. The facility will consist of a single fully steerable 30 m dish located at an altitude of 3,000 m in the Sierra Nevada in the south of Spain near Granada and an interferometer of three 12–15 m fully steerable and moveable antennae with a baseline of 1.5 km x 0.8 km located at 2,500 m in the Plateau de Bure near Grenoble. In exchange for offering a site and a local headquarters in Granada, Spanish astronomers will get about 10% observation time at both observatories. The main office of the Institut de Radio-astronomie Millimetrique (IRAM) in Grenoble will house 20–25 people by the end of 1979. The construction order for the large dish is ready to be placed and design of the interferometer is in the initial stage with the dish expected to be operational in 1982 and the interferometer in 1986. Millimetre range astronomy covers cold thermal sources (a 10° blackbody peaks at 1 mm wavelength) including planets, asteroids, and dense interstellar molecular dust clouds.

Costs may boost UK energy conservation: An inter-Departmental report by officials under the chairmanship of the Department of Energy declares that higher prices will "provide scope for considerable further savings" as the price of oil in particular is expected to double by the end of the century. Higher prices form a principal part of the government's recommended strategy and it stresses that economic energy pricings should "reinforce conservation measures and not work against them." This is believed to be a reference to the relatively low price of petrol in the UK which many politicians would like to see raised. A Department of Energy spokesperson said that "the Government should not take measures to cut fuel prices." Other measures in the government's strategy include: information; "a good example from Government"; and specialised advice and training. Research and development, expected to rise to £30m per year, is believed to be adequately funded at present. There are to be no mandatory controls on industry, which consumes the largest share (39%) of the UK's energy budget. The large energy users (50% of industrial energy is consumed by 14 firms and 70% by less than 200 firms) are believed to have an incentive to save energy voluntarily and the report argues that "mandatory measures would increase the burden on industry and would operate against the immediate need to increase industrial efficiency and competitiveness." Energy Conservation: scope for new measures and long term strategy Energy Paper Number 33. HMSO £2.

Europe moves further towards independent space capability: The remote sensing board of the European Space Agency (ESA) approved, on 15 March, the start of a remote sensing preparatory programme to develop the technological systems necessary to monitor both land and ocean surfaces. The preparatory programme will be for two years with the sizeable budget of nine million accounting units. (The 1979 ESA budget is 573 MAU with large individual programmes such as Exosat and the space telescope costing 25 MAU

and 15 MAU respectively.) Denmark, France, Italy, Netherlands, Sweden, and the UK have already subscribed and other member states are expected to join shortly. The programme will depend heavily on independent national development programmes as well, such as the multi-mission platform being developed in France and the synthetic aperture radar system being developed in Germany, both of which are being prepared for use in Spacelab flights in 1983.

Moscow Radio criticises US scientists: US scientists participating in the growing "SOS" (Scientists for Orlov and Shcharanskii) campaign has been severely censured by Moscow Radio's English-language service to North America. The 2,000 or so signatories of the SOS protest pledge themselves to refrain from taking part in certain specific forms of exchange programme with the Soviet Union until Orlov and Shcharanskii are released and cleared of the charges of anti-Soviet activity for which they were sentenced last year.

According to Moscow Radio, the SOS participants are misinformed and chauvinistic—the latter term since they are acting on the "assumption that only the Soviet Union will suffer" from such severance of ties. The commentator stated that, on the contrary, research from Tokamak and "many other achievements of Soviet science" are used in US laboratories, and that in any case, all blockades—political, economic and diplomatic—of the Soviet Union have failed in the past. This broadcast took place on the same day that a group in Britain announced the formation of a "Lerner Circle" to campaign for Aleksandr Lerner, the cyberneticist and a "refusnik" of eight-year's standing to be granted an emigration visa. Among the founding members of the "circle" are Max Perutz, Nevill Mott and Rodney Porter.

US to increase scientific cooperation with Brazil: The United States is to expand its scientific cooperation with Brazil as part of an effort to increase the relations between the two countries, Vice-President Walter Mondale said on a visit to the country's capital, Brasilia, last week.

Mr Mondale said that the Brazilian president, General Joao Baptista Figueiredo, had accepted an invitation to send the president's science advisor, Dr Frank Press and a team of specialists to consult with Brazilian scientists on the form that this cooperation might take.

Little was said during the Vice-President's visit of previous US criticism of Brazil's nuclear power programme, in particular its plan to import reprocessing facilities from West Germany as well as nuclear plants.

New Windscale leak discovered: Borehole sampling in the vicinity of a temporary storage tank at British Nuclear Fuel Ltd's reprocessing plant at Windscale, Cumbria has shown a marked increase in radioactivity. The temporary storage tank holds highly active liquid wastes dissolved in nitric acid for concentration by evaporation after which the waste is transferred to highly active waste storage silos. A BNFL spokesman said that the activity in the borehole was 1% of that in the temporary tank which in turn was 1% of that in the highly active tanks but said that the precise level of activity was "unavailable." Borehole monitoring was initiated two years ago when 200 gallons per day of liquid waste was found seeping into the soil around one of the concrete storage silos. This leak has not been located but the area has been isolated and the radioactivity is believed to be retained in the soil, as tests of ground water have shown no increase in activity.

correspondence

Nuclear decisions

SIR,—In a recent article (22 February, page 594) Peter Taylor calls for changes in the way in which decisions are taken on nuclear energy matters. The article contains two straightforward issues and two more complex ones of interest to the Health and Safety Executive. Let me first discuss the straightforward points.

The first is the reference to the alleged assumption that the issues are "primarily 'scientific' and 'technical', and thus... the exclusive field of experts". I doubt if anyone really makes this assumption these days. It is certainly not a view held in the Health and Safety Executive.

The second issue relates to the Hinkley Point incident, which Peter Taylor has seriously misunderstood. The ministerial statement, to which he refers, makes it quite clear that the coolant involved was not the core coolant, which is carbon dioxide, but the sea water coolant for auxiliary equipment. Cooling was maintained by a jury-rigged system involving a fire pump. The reactor coolant was unaffected.

The most important of Peter Taylor's points relates to risk assessment. He casts quite legitimate doubts on the accuracy with which quantitative probability estimates can be made for various scales of accidents and their consequences. He goes on, however, to say that "probabilistic presentation obfuscates rather than illustrates the potential effects". On this I think he is wrong. The study of the range of accidents and consequences, including very serious ones, is helpful and is standard practice. The search for a worst case is less useful because of the difficulty of defining "worst". The worst case owes more to the imagination and inventiveness of its postulator than to reality. More seriously, the discussion of a worst case diverts attention and effort away from the more likely accidents. Moreover, a study of very serious accidents without reference to their likelihood does not provide any basis for decisions. Thus, for example, the worst possible accidents in many forms of transport, chemical processing and gas distribution would be unacceptable if they occurred frequently; it is the very low probability of these serious accidents that makes these industries acceptable in a society which relies heavily on the benefits they bring. It would be wrong to ban large passenger aircraft just because one might, one day, crash into a crowded stadium. It would be wrong precisely because the probability is very low, even though the consequences would be very severe.

Of course the probability and scale of accidents do not alone provide a definitive basis for decisions on, in particular, the licensing of nuclear installations. They do, however, provide an essential input.

The final point of importance relates to the supply of information. Peter Taylor writes of "a retreat into secrecy" but the alternative, moving towards greater openness, is not without difficulties. Much of the information in the detailed safety

assessment of a plant is owned by the designer and is of real commercial value to him. So long as we expect to have a commercial structure, nationally or internationally, to our nuclear industry this point will limit disclosure. I believe, and have said so in public, that there is too much use of the claim for commercial value and that we ought to move towards a more open situation. But this requires additional resources, both in the industry and in the Executive, and my hand is not strengthened when published information is misquoted and misused. The "selective use of the results of scientific research" is not confined to any one group.

H. J. DUNSTER

Health and Safety Executive, London

SIR,—Peter Taylor (22 February, page 594) refers to the safety target which I proposed in 1967. He is right in quoting my view that the setting of a target in no way gives assurance that the target is or will be achieved.

Both the Flowers Report and the recent report of the Lewis Commission (USA) strongly support the use of fault trees and event trees for licensing purposes and to direct the research programme. Lewis also supports the Rasmussen methodology. Use of these techniques necessarily requires an adequate data base.

The Safety and Reliability Directorate (SRD), originally under my direction, have worked extremely hard during the last 13 years to collect relevant data and develop the highly disciplined and critical assessment techniques. These are now used in the nuclear industry and are being more widely used in the chemical and allied industries in association with over 60 agencies and major companies in over 16 countries.

I know that numerical assessment is not perfect and is not enough in isolation to determine design and operation but, rather than obfuscate, the need to obtain data and analyse quantitatively wonderfully sharpens the mind and illuminates the problem, even if to show up its difficulties.

In my view the use of emotive words such as credible, incredible, maximum credible, did much to confuse safety issues in the first 10–15 years of reactor design.

Taylor asks that the worst condition should be stated. There is seldom a "worst". By assuming a combination of more and more unlikely events I am sure that I could develop a hypothetical situation to beat Mr Taylor, but of what value would this be?

When referring to the AGR and the NRPB/NII study Mr Taylor quotes 100,000 and 600,000 casualties. The reader might reasonably believe this to be deaths, but paragraph 266 of the Flowers Report clearly states that the major effect would be thyroid damage. The number of deaths were estimated to be around about 300/400 although this number could be an order of magnitude higher or lower.

As to the fast reactor, the Flower's Report (paragraph 304) states, "The consequences of such accidents would be so severe that the FBR could scarcely

be contemplated on an extensive commercial basis unless it is established with a very high degree of confidence that reactivity accidents can be controlled so as to prevent gross fuel vaporisation." It is still my view and that of my colleagues that gross fuel vaporisation is highly improbable, and many international research programmes still continue to provide further evidence on this point.

I support Mr Taylor's desire to ensure a highly critical approach on safety matters. We have done much to improve the standard of objective criticism in the UK, but I invite Mr Taylor to be equally concerned about the safety of man and the environment in all our industry.

F. R. FARMER

Atomic Energy Authority

SIR,—Peter Taylor (22 February, page 595) states "... We were able to run NRPB calculations (which were for a notional site) for a specific locality (we chose Kalkar in Wes. Germany). We discovered that NRPB had chosen not to present their own work calculations—the results of one weather category which led to 600,000 casualties. Our site-specific study, having altered only the population data on the programme, produced over 900,000 casualties". Perhaps this concise account disguises the actual situation and I should like to reply in the absence abroad of Dr G. N. Kelly, the principal author.

When NRPE published its initial study of consequences of notional fast reactor accidents (Kelly, G. N., Jones, J. A. and Hunt, B. W., An estimate of the radiological consequences of notional accidental releases of radioactivity from a fast breeder reactor, NRPB-R53), it stated that "further analyses are being undertaken to assess the sensitivity of the results to variations of the more important parameters". At that stage no calculation of the type referred to by Mr Taylor had been done. In fact, the first sensitivity analysis has just been published (Kelly, G. N., Jones, J. A. and Simmonds, J. R., The influence of the physico-chemical form of the aerosol on the radiological consequences of notional accidental releases of radioactivity from a fast breeder reactor, NRPB-R73). Further studies are in hand which will include variation in meteorological conditions and population densities, from the likely parameters used in the initial study to the remote but nevertheless possible extremes. It is notable that the Political Ecology Research Group itself showed (RR-1, A study of consequences to the public of a severe accident at a commercial FBR located at Kalkar, West Germany) that the increased magnitude of the consequences in the worst conditions is broadly compensated for by the lower frequency of occurrence, giving comparable risks.

When NRPB has completed its investigations they will be published through HMSO.

Opioid peptides and their relatives

from John Hughes

MORPHINE appears to produce its analgesic pharmacological effects by mimicking the action of natural endogenous opiate peptides. Recent research has illuminated various aspects of the origin and physiological relevance of these peptides.

The critical structure responsible for opiate peptide activity is Tyr-Gly-Gly-Phe(X) where X is a hydrophobic amino acid such as methionine or leucine in Met and Leu-enkephalin. Either N or C-terminal extension of these sequences preserves opioid activity to some degree although an N-terminal block, acylation, for example, abolishes activity. H. R. Morris originally noted the homology between the β -lipotropin (LPH) sequence 61–65 and Met-enkephalin, and the relationship between LPH, Met-enkephalin and β -endorphin (LPH 61–91) has since received considerable attention. All fragments of LPH commencing with residues 61–65 have opioid activity to some extent although peak activity is seen with Met-enkephalin and the C-terminal fragment of β -endorphin. This has posed problems in determining the possible biological significance of a given sequence, particularly since a number of active fragments of LPH have been isolated from pituitary extracts. However, it now seems likely that proteolysis during extraction accounts for the presence of most of the α and γ -endorphin (LPH 61–76 and 61–77) in pituitary extracts (Rossler *et al. Life Sci.* **21**, 847; 1977). LPH 61–77 (γ -endorphin) may in fact be in the first metabolic product of β -endorphin allowing the final inactivation by amino peptidase which does not attack intact β -endorphin.

There is now overwhelming evidence that a family of related lipotropin/corticotropin intermediate lobe peptides are derived from a common glycoprotein precursor of molecular weight ~30,000 (Mains, Eipper & Ling *Proc. natn. Acad. Sci. U.S.A.* **74**, 3014; 1977; Roberts & Herbert *Proc. natn. Acad. Sci. U.S.A.* **74**, 4826; 1977). Bio-

synthesis of β -endorphin from β -LPH and its precursor (pro-opiocortin) has been demonstrated with radiolabelled pulse chase experiments in the pars intermedia (Crine *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 4719; 1978) and there is evidence that corticotropin and lipotropin/endorphin activity is present in the same secretory granules (Weber, Voigt & Martin *Brain Res.* **157**, 385; 1978).

The mRNA encoding for pro-opiocortin has now been purified from bovine pituitary intermediate lobe (Nakanishi *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 6021; 1978) and a further report in this issue of *Nature* (Nakanishi *et al.* page 423) now describes the full nucleotide sequence of this mRNA following cloning of the cDNA species in *Escherichia coli*. Inspection of the corresponding amino acid sequence reveals a number of interesting features. The molecule itself seems to consist of four repetitive units based on the MSH/ACTH core sequence, these units are separated by paired basic residues. ACTH and β -lipotropin exist as contiguous peptides at the C-terminal and are separated by the Lys-Arg sequence. Thus, in common with other protein precursors, the biologically active sequences are flanked by paired basic residues at which proteolytic processing takes place. An exciting and novel aspect of this study is the recognition of a new MSH sequence termed γ -MSH, this sequence is also flanked by paired basic residues and by implication could be of physiological significance. Nakanishi *et al.* postulate that the structural gene for pro-opiocortin may have evolved through a series of sequence duplications of certain common ancestral DNA segments, other modifications occurring through substitution, addition or deletion of some regions.

The existence of so many potentially active molecules in one precursor is a subject of much interest. The question of how pro-opiocortin cleavage is regulated is thus an intriguing and important one. Are all the possible

peptide sequences processed and released or do controlling and inactivating mechanisms exist? Relatively little is known of these mechanisms and the enzyme(s) responsible for sequence cleavage remain to be isolated. There is evidence that these control mechanisms may alter during development (Silman *et al. Nature* **276**, 526; 1978). Thus α -MSH, CLIP (ACTH 18–39), β -MSH and β -endorphin predominate in the fetal pituitary of the rhesus monkey whilst ACTH, γ -LPH and β -LPH predominate in the adult. Similar changes in these patterns of peptide production may occur in the adult in response to pathological states or changes in hormone balance. The identification of N-acetyl forms of β -endorphin (Smyth *et al. Nature* in the press) may reflect one controlling mechanism whereby acetylation inactivates the opioid peptide whilst leading to activation of α -MSH. The activity of the acetylating system could thus determine the balance of biological activities between these two peptides and could provide another point of disturbance leading to altered neuronal activity and mental states.

Pro-opiocortin is a glycosylated peptide and glycosylation may be important for protection of the prohormone from nonspecific proteolysis during packaging and could also direct cleavage of specific sequences through conformational effects. A recent paper by Loch and Gainer (*FEBS Lett.* **96**, 769; 1978) illustrates this view. Tunicamycin inhibits glycosylation and although it does not prevent synthesis of un-glycosylated pro-opiocortin there is a rapid degradation of this un-glycosylated species with the production of atypical peptides. Conceivably a disturbance of glycosylation in pathological states could lead to the production of 'abnormal' neuropeptides with undesirable side-effects on neuronal function.

John Hughes is Reader in Pharmacological Biochemistry, Department of Biochemistry, Imperial College, London

Despite the presence of the Met-enkephalin sequence in β -LPH there is no evidence that β -LPH acts as a precursor for methionine-enkephalin. Neurones immunoreactive to β -endorphin, β -LPH, ACTH and α -MSH have been found in the brain (Bloom *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 1591; 1978; Watson *et al. Science* **200**, 1180; 1978; Jacobowitz & O'Donohue *Proc. natn. Acad. Sci. U.S.A.* **75**, 6300; 1978). It is not clear whether this is one single neuronal system, although the localisation of cell bodies in the hypothalamus and their projections to other brain areas are very similar; however these neurones may be clearly distinguished from the more diffuse enkephalin immunoreactive neurones (Watson *et al. Nature* **275**, 226; 1978). As β -endorphin/LPH antibodies also recognise pro-opiocortin but do not react with enkephalin cell bodies or neurones, it seems unlikely that a common precursor is involved. Studies on the incorporation of ^3H -Tyr into the enkephalins have shown that these peptides are locally synthesised in gut and brain and that synthesis may be blocked by protein synthesis inhibitors (Sosa *et al. FEBS Lett.* **84**, 195; 1977; McKnight *et al. Proc. Roy. Soc. Ser. B* in the press). The nature of the enkephalin precursor(s) is therefore of considerable interest. Recent work has thrown

some light on this problem (Lewis *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 4021; 1978). Extracts of striatum contain proteins (molecular weight 40,000 and 100,000) that yield opioid peptides on tryptic digestion, these peptides can be distinguished from LPH fragments by high pressure liquid chromatography. These findings may explain the presence of unidentified opioid peptides in the brain and striatum (Hughes *et al. Br. J. Pharmac.* **61**, 639; 1977; Yang *et al. Neuropharmacology* **17**, 433; 1978) since they could be intermediate products resulting from the conversion of pro-enkephalin to enkephalin.

Kangawa *et al. (Biochem. biophys. Res. Commun.* **86**, 153; 1978) have identified a new peptide containing leucine-enkephalin in pig hypothalamus. This 15-residue peptide, rather unfortunately in my view termed α -neo-endorphin, contains the leucine-enkephalin sequence followed by the basic sequence -Arg-Lys-Arg-, an observation which supports the concept of a separate enkephalin precursor. Studies in our laboratory indicate the presence in brain of other opioid peptide sequences in much greater amounts than those found for α -neo-endorphin and the relationship between these peptides will be of considerable interest. Also, their existence sounds a cautionary note for those of us using immuno-

assay and immunocytochemical techniques in view of possible cross-reactivity and misinterpretation.

Enkephalin immunoreactivity has also been detected in cells of the anterior pituitary producing growth hormone (Weber *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 6134; 1978). Could it be that growth hormone and methionine or leucine-enkephalin share a common precursor? A common precursor for both enkephalins is also a possibility and this would explain the apparent coexistence of these peptides in the same neurones although this has yet to be demonstrated conclusively.

The application of recombinant DNA techniques is relatively new to this field but it is likely to prove a powerful and original approach. Nakanishi *et al.* suggest that the nucleotide coding regions for ACTH/LPH may have evolved by a series of genetic duplications since the cloned DNA insert for pro-opiocortin is characterised by unusually high C+G nucleotide base contents and also by numerous DNA sequence duplications. Other neuropeptides also probably evolved in this fashion although nothing is known at present as to the origin of molecules such as substance P or neurotensin. The further unravelling of the various protein-peptide relationships is likely to prove both fruitful and exciting. $\square$

The representation of three-dimensional objects

from N. S. Sutherland

THE tasks carried out by the human brain are so complex that the only way in which to specify precise theories of how they are executed is to construct computational models. It is at present not possible to construct formal proofs to demonstrate what a complex but well specified series of information processing operations will accomplish. The number of operations needed to perform such tasks as the recognition of visual objects is so vast that we can only be sure that a given model actually accounts for successful performance if we translate it into a computer program and demonstrate that the program when run executes that task. Few, if any, such programs run successfully at the first attempt, but the discipline imposed by writing them and the study of the ways in which they fail generate insights into the structure of the task and the structure of the operations needed to carry it out.

A working computational model of task performance becomes a candidate for a theory of how the brain itself performs that task. Because of their complexity it is sometimes difficult to test such models experimentally, but in principle and with sufficient ingenuity they can be subjected to the same experimental tests and their plausibility evaluated in exactly the same way as the vague theories normally proposed by psychologists or the even vaguer ones sometimes advanced by physiologists.

In 1976, David Marr¹ proposed a computational model of how the brain recovers from the grey scale data present in the retinal image a two-dimensional description in which lines and edges are explicitly represented: he called this description 'the primal sketch'. The processes suggested by Marr are extremely complex, but his theory is both compatible with physio-

logical findings on the early stages of analysis in the visual system and also enables us to understand why the system is organised in the way that it is, given the requirements of the task it has to carry out.

The problem of three-dimensional vision

Virtually nothing is known about the physiological and anatomical arrangements that mediate the next stage of vision, that is the mechanisms that take as input the primal sketch containing information about the presence of lines and edges in the picture and compute a three-dimensional representation of the objects towards which the eyes are directed. In the 'sixties and early 'seventies, however, some programs²⁻⁴ were developed that successfully recovered a three-dimensional description of a scene from a line drawing. Most of this work was restricted to scenes containing only plane-faced polyhedra. Moreover, the 3-D descriptions formed were for the most part very impoverished. They usually

Professor N. S. Sutherland is Director of the Centre for Research on Perception and Cognition at the University of Sussex.

Fig. 1 Within each rectangle is shown on the left the 'model axis' for that level of description and on the right the way in which the model is broken up into component parts. The level 1 module represents the whole object, and the finer details of the arm, forearm and hand are represented respectively at levels 2, 3, and 4. At each level other than level 1, there would of course be many other modules representing for example the decomposition of the head, the nose and so on. Note that the body or component part represented at each level is decomposed into sub-components that are all of approximately the same size. (This figure is based on ref. 5.)

specified only the local relationships between pairs of surfaces in the scene: for example, two surfaces can be described as joining at a concave or convex edge or one surface may lie in front of another and partially obscure it. Even if additional information (such as the precise angle between two surfaces joined across an edge) is recovered and recorded, this kind of description is clumsy: considerable additional computation would be required to specify explicitly the different parts of an object and how they are related to one another. Moreover, anyone viewing an object has a strong impression of the volume of space it occupies and such information is not explicitly provided by a description that specifies only the relationships between neighbouring surfaces.

The construction by the brain of 3-D representations of objects serves two functions. First, in order to manipulate objects and to avoid bumping into them, organisms must be able to perceive the disposition of their surfaces in space. Second, in order to recognise an object and evaluate its significance for action, it is necessary to build a 3-D representation from the retinal image and then to match that description to a stored 3-D representation of the object. To facilitate the recognition process, it is likely that the representation constructed in immediate perception is similar in form to the stored representations with which it has to be matched in order for recognition to occur. In practice, the two processes—construction and matching—cannot be rigorously separated since, as will be

shown below, the construction of a perceptual representation may itself be guided by stored models of what is likely to be present in the environment.

The Marr and Nishihara model

Marr and Nishihara⁷ have recently made a fresh attack on the problem of how the brain represents information about 3-D objects: their proposals overcome some of the limitations of previous work. They lay down three criteria that such representations should satisfy in order to account for the efficiency with which the human visual system recognises 3-D objects.

Criterion (1) The representation should be easy to compute from the pictorial image.

Criterion (2) It should provide a unique description of any object which we are able to distinguish and the description should be canonical in the sense that the same object seen from any point of view will always yield the same unique description.

Criterion (3) Different representations should reflect the similarity between different objects whilst also preserving the differences: it is important to be able to recognise both that a shape is a man and that it is Jones or Smith.

One way of describing an object in three dimensions would be to compute the slope relative to the line of sight at each point on the visible surface of the object and the physical distance

between different points on its surface. Such a representation would be extremely cumbersome and would not satisfy criterion (2) since it would vary with changes in the observer's viewpoint. Marr and Nishihara argue for a volumetric description that is independent of viewpoint. To obtain such a description, some axis intrinsic to the object has to be selected to which the rest of the description can be referred: Marr and Nishihara term such an axis 'the model axis'. If the description of the same object seen from different points of view is to be canonical (criterion (2)), it is essential that when the same object is viewed on different occasions and from different viewpoints, the same model axis must be selected. For an elongated object, its longest dimension yields such a canonical model axis, and Marr and Nishihara only consider in detail objects of this sort. They suggest, however, that for some objects that are not elongated, like typewriters or armchairs, symmetry could be used to yield a canonical model axis. It is worth nothing parenthetically that for many objects commonly found in the same orientation, the visual system may select as a model axis the gravitational vertical.

Marr and Nishihara propose that objects are decomposed into their component parts. This proposal accords with our intuitions and has been previously made by others including myself⁸: some of my own experiments^{7,8} have indeed demonstrated that object recognition even in rats and goldfish is based on decomposing objects into their component parts. The originality of this aspect of Marr and Nishihara's work lies in their attempt to specify rigorously how such decomposition is effected, how the parts and their relationship to one another are described, and how the decomposition into parts can be used to facilitate the process of visual recognition.

In their theory the shape of each part is described as a generalised cone, that is, in terms of the surface swept out by a cross section moving along an axis and smoothly varying in shape and size. Binford⁹ was the first to suggest the use of generalised cones in the representation of 3-D objects, but Marr and Nishihara carry his suggestion much further by showing how it is possible to specify uniquely and simply the dispositions of the component parts of an object in terms of the relationships between the axes of the generalised cones by which they are represented. An important feature of their theory is that the descriptions are hierarchical: an object is first broken down into its main components and each of these is broken down into successively smaller sub-components.

Figure 1 illustrates such a representation. For an elongated form like that of a man, the longest axis is picked as the model axis and information is added about its length and the shape of the generalised cone that best approximates to the volume of space occupied by the whole shape. The object is next decomposed into its largest components and the component to which most other components are joined is then selected as 'the principal axis' for that stage of the description. Note that although in Fig. 1 the orientation of the principal axis of the whole form happens to be the same as that of the model axis, the two axes need not necessarily have the same orienta-

tion. Whereas the model axis depends on the direction of elongation of the whole body, the principal axis is the direction of elongation of the major component to which most other major components are joined. The orientation of the principal axis is specified in relation to the model axis: the angles and positions at which all other components join the principal axis are also recorded. The human form is most naturally decomposed initially into trunk, head, arms and legs with the trunk forming the principal axis. Where, as in the case of the arms and the trunk, the angle formed between one component axis and the principal axis is variable, information about the range of possible angles would also need to be stored. Figure 1 shows how in further modules the left arm can be decomposed into upper arm and forearm, with the forearm in turn decomposed into forearm and hand, and the hand into palm and fingers.

The resulting representation of a three-dimensional object is independent of viewpoint (criterion (2)), volumetric and modular. Marr and Nishihara call attention to three important advantages of modularity. First, it satisfies criterion (3): the similarity between objects can be extracted by examining the coarse representation of their major components, whilst small differences can be read off from modules that provide finer detail. Second, the model's modular construction makes it possible to effect changes in one module without disrupting others. Third, it facilitates recognition both of whole objects and of their parts.

Marr and Nishihara suggest a method of computing this type of representation from the visual image (criterion (1)). They consider primarily the construction of 3-D representations from silhouettes of objects: further details of the computational processes that effect the decomposition into parts and the assumptions underlying them can be found in Marr¹⁰. Figure 2 shows one way in which the main component axes may be recovered from the outlines of a donkey by segmenting the figure at its principal inflection points. Although this decomposition into component parts each with its own axis was achieved by a computer program, it is hard to evaluate how far the program would succeed with a range of other objects and how far it would succeed in producing the same segmentation with different viewpoints.

Even if the same segmentation is achieved, the initial description in terms of generalised cones and the relation between their axes will differ depending on viewpoint. In viewing real 3-D scenes, this problem can largely be overcome by taking into ac-

count cues (such as stereopsis and motion parallax) to the distance of different parts of the figure from the eye: such cues make it possible to compute the real length of the different axes and the real angle between one axis and another. Difficulties arise when the observer is presented with a two-dimensional picture of an object seen from a viewpoint that results in the foreshortening of the model axis. Marr and Nishihara consider a number of ways of dealing with this problem. If any part of an object can be recognised (for example, the foot of a horse), it would be possible to recover the stored representation of the whole object, and use that representation to guide the interpretation of the remainder of the picture. Moreover, the relative positions at which different parts of a body are joined to a principal axis are little affected by foreshortening and this information could again be used to retrieve the correct stored representation. Once the stored representation has been accessed, it is possible to estimate the orientation of the model axis with respect to the observer's viewpoint and to compute whether given this orientation the details in the image correspond to the model held in memory. Marr and Nishihara specify how this process may be carried out: it involves computing a 3-D representation of the object in viewer-centred coordinates, and adjusting the estimate of the orientation of the model axis by moving backwards and forwards between this representation and the representation stored in memory in object-centred coordinates.

Evaluation of the model

There are several difficulties in Marr and Nishihara's theory as developed so far, the first of which they note themselves. First, it is not clear that it would be possible to pick a model axis which remained the same for any given object regardless of viewpoint. As already noted, apart from the difficulties with objects that are not elongated, problems arise with elongated objects that are very foreshortened. This apparent drawback may in fact constitute one of the theory's strengths. Foreshortened pictures of common objects, for example, a pail or a telephone seen from directly above, are in fact very difficult to recognise (see Fig. 3). Second, it is not clear that it will always be possible to decompose the same object seen from different positions in the same way. Although at any level of modularity, the system is supposed to recover components of roughly the same size, decisions must be to some extent arbitrary. In Marr and Nishihara's own example (Fig. 1) an arm could be as readily decomposed

Fig. 2 The contours formed by the silhouette of a body composed of generalised cones can be used to locate the projections of its natural axes provided that they are not severely foreshortened. One method of decomposing the body and recovering the axes of the parts is shown in this example from a programme written by P. Vatan. The initial outline (a) was obtained by applying local grouping processes to the 'primal sketch' of an image of a toy donkey. This outline was then smoothed and divided into convex (pluses) and concave sections (minuses) (b). Next, strong segmentation points, like the deep concavity circled in (c), are identified and a set of heuristic rules are used to connect them with other points on the contour to produce the segmentation shown in (d). The component axes shown in (e) were then derived. The thin lines in (f) indicate the junctions of the head, leg and tail components to the torso axis, and of the snout and ear components to the head axis (figure and legend based on ref. 5).

Fig. 3

upper-arm, forearm and hand as into upper-arm and forearm (with the latter being decomposed in a further module into forearm proper and hand). The problem of decomposition into components of approximately the same size becomes particularly acute if some of the components are very foreshortened. Failure to decompose an object in the same way would make it difficult to match the initial representation of the object to the representation stored in memory. Third, the model seems in some ways to exceed the capacities of human vision. Rock¹¹ and others have found that elongated 2-D shapes are not readily recognisable when rotated in the picture plane unless the observer has had experience of seeing them in several orientations.

The proposed model does, however, have many new and useful features. As stressed above, the theory facilitates the computational processes underlying object recognition. It is virtually the first attempt to specify a general theory of the form in which visual representations of 3-D objects are stored. It is an advance on most previous theories in that it handles objects with curved surfaces and silhouettes of objects: although there is less difficulty in constructing unambiguous representations when viewing the real world directly, people can form 3-D representations from silhouettes and it is necessary to account for this capacity.

Moreover, in addition to its computational power, the model has in my opinion considerable plausibility on psychological grounds. First, in looking at an object we are simultaneously aware both of its visible structure with respect to our viewpoint and also of the volume of space it occupies: Marr and Nishihara compute both of these representations and give good reasons why it is necessary to do so. They show

how recognition can be facilitated by adjusting a representation in viewer-centred coordinates by fitting it by successive approximations to a stored model which is independent of viewpoint. It might be added that no matter how much constructing a description that is independent of viewpoint facilitates recognition, it would still be necessary to build a description in terms of viewer-centred coordinates in order to manipulate objects. Second, their model explains the difficulty experienced in recognising pictures of foreshortened objects. Third, although Rock¹¹ found that recognition of elongated objects rotated in the fronto-parallel plane was difficult, they were easier to recognise under rotation than objects that were not elongated. Fourth, as Marr and Nishihara note, there is evidence that people sometimes refer the description of the parts of an object to its longest axis. One instance, to which Mach¹² was the first to draw attention, is shown in Fig. 4. The single large diamond is seen as a diamond—its description is referred to its vertical axis; the diamonds forming a diagonal line are, however, usually seen as squares—their description is referred to the orientation of the model axis defined by the direction of elongation of the whole line. Finally, the theory captures our intuition that in viewing an object we see it (and verbally describe it) as composed of discrete parts each occupying a volume of space. Moreover, if it is assumed that it is possible to be conscious of the details of only one of the modules at a time, the theory satisfies our intuition that we cannot simultaneously form an image of the general shape of a man and of the details of the shape of his left ear.

The problem to which Marr and Nishihara address themselves is how

Fig. 4 The single diamond is seen as a diamond because its orientation is perceived with respect to the vertical; but the diamonds in the oblique line tend to be seen as squares because their perceived orientation is determined by their relationship to the diagonal line of which each is a part.

we recognise a given object as a member of a class of objects all of which have the same basic physical shape. It is worth noting that there is a further and even deeper problem of visual perception to which neither they nor anyone else have provided any solution. This problem is how we recognise the category to which a new object belongs when the new example has little or no similarity of shape to examples previously encountered, but does have the same function. Chairs come in a great variety of shapes and sizes and all they have in common is that they are man-made objects having a surface suitable to receive the weight of the human bottom and another fitted to support the human back. Nevertheless, we have little difficulty in recognising, even when first encountered, bizarre new chairs thought up by futuristic designers: in order to do so, we must integrate our knowledge of the function of chairs with the 3-D description formed of the new example.

It has of course been impossible to present here more than an outline of Marr and Nishihara's paper which contains many subtle points of detail. As with all Marr's work, the decisions he has taken in theory construction are always motivated: there is none of the 'I put that in because it seems to work, goodness knows why' attitude that characterises the *ad hocery* of some practitioners of artificial intelligence. Marr and Nishihara's paper provides a starting point, not a finished theory. Nonetheless, it contains some brilliant insights into a deep, complex, and much worked over problem, and it is possible that in a few years' time it will be regarded as a classic. □

The Ice-age Amazon

from Paul Colinvaux

A MAP has been published by Ab'Saber (*Paleoclimas* 3, 1; 1977) which shows the Amazon basin to have been largely without closed forest during the last ice age. Wet forest was restricted to the eastern flanks of the Andes, to the mountains of Guiana in the north, along the coastal escarpment of eastern Brazil, up which there now climbs the spectacular highway linking São Paulo with its port of Santos, and in scattered patches along the Amazon river system. This map is the most definite statement yet of a growing consensus that equatorial South America has been subjected to major climatic change. The importance of this to both climate dynamics and ecological theory is very great.

The most persuasive direct evidence for environmental change in the Amazon basin is the existence of dissected and gullied land surfaces now covered by closed forest. These surfaces were revealed by side-scan radar from aircraft in surveys made by the Brazilian government. Complete maps from the side-scan survey do not seem to have been published but I was assured in Brazil that the coverage is extensive. Both Tricart (*Rev. Geomorph. Dynamique* 23, 145; 1975) and Bigarella & Becker (*Bol. Paranaense Geosci.* 33, 171; 1975) have given accounts of the fossil land forms, showing that at times in the Pleistocene wide stretches of the Amazon cannot have supported closed forest. Ab'Saber's map is a further compilation of these data, coupled with the results of many years of geological and soil survey. Dating of the dissected surface is still weak but Bigarella & Becker show that outside the Amazon basin near São Paulo, the last episode preceded a radiocarbon date of 10,000 b.p., thus allowing the event to be synchronous with northern glaciations.

The ice age climate of equatorial America is also charted in the high Andes and in the Galapagos Islands. Andean lakes from Titicaca in Peru to Bogota in Colombia have retreated from shorelines of much larger lakes in the recent geological past. The shorelines themselves have not yet yielded radiocarbon ages of their occupancy, but a powerful argument suggesting that the larger lakes were associated with glaciations comes from studies of end moraines abandoned by the Quelccaya ice-cap in Peru. The Quelccaya is the world's third ice cap, perched improbably on the mountains within 14° of the equator. Continuing mass-balance studies of the ice-cap by

Thompson *et al.* (*Science* 203, 1240; 1979) show that precipitation must be heavy to offset the high annual ablation and that an ice-cap can only be maintained when clouds shield the ice for many months each year. Extension of the ice-cap in the past, therefore, implies increased precipitation and cloud, conditions which would favour enlargement of the lakes and suggesting that their growth was synchronous with Andean glaciations.

Finally there is well-dated sediment sequence from the Galapagos Islands which shows that the moist highlands, which are now shrouded by stratus cloud and fog-drip, were dry from 10,000 b.p. to a time beyond the reach of radiocarbon dating (see *Nature* 240, 17; 1972). The Galapagos record has the securest dating, encouraging the impression that climate along an equatorial strip across the continent suffered many changes during the last glaciation of the northern hemisphere. There was increased dryness at the Galapagos to the west, increased wetness in part of the high Andes, and a lack of forest cover in the Amazon basin (suggesting seasonal rain and drought) all the way across the continent to the edge of the coastal escarpment in the east. A possible implication for climate dynamics is that the Intertropical Convergence Zone (ITCZ) was largely obliterated in glacial times, as it is in Africa. At least there seems good reason for thinking that the zone was neither to the south nor to the north of its present position (see *Nature* 240, 17; 1972; 245, 91; 1973). But the more exciting implications are for ecological theory. A review of the latest data on the distribution of modern taxa by Simpson and Haffer (*Ann. Rev. Ecol. Syst.* 9, 497; 1978) is thus of great interest.

There are many Amazon data about butterflies compiled from the very large collections which have been continually growing since the first of their kind by Waterton and Wallace in the last century. Bird data are also more complete than one might expect and have been supplemented by less complete collections of lizards and some plants by Simpson and Haffer. The data show that there are many, highly local, definite, disjunct distributions. What is more, the disjunctions can be shown, particularly with the butterfly data, to be bordered by zones where arrays of hybrids are normal. Turner (*Evolution* 25, 471; 1971) compared the marking of modern hybrid butterflies with those illustrated in Dutch books of the 18th century and showed that the same hybrids have been produced for 200 yr, or 2,000 generations, making plausible the postulate that the present patterns of distribution are not changing rapidly. As these patterns of distri-

bution define patches within continuous rain forest today, Simpson and Haffer seek their origin in the past. They postulate that each centre of distribution represents a forest refuge in the more seasonal or drier climates of the last ice age. In a footnote to their paper they suggest that the forest refuges shown on the Ab'Saber map can be reconciled with these modern centres of distribution.

The figure shows sketch-maps of the region for modern topography, modern rainfall, and a summary of dispersal data for butterflies. Very approximate boundaries for the ice-age forests of Ab'Saber are added to the butterfly map.

There is a strong and obvious synchrony between many butterfly distributions and the postulated forest

a, Modern topography; b, modern rainfall; c, distributions of modern butterfly populations (shaded) and ice age forest refuges estimated from fossil land forms (dashed lines).

refuges but these tend to be along the mountains or escarpments that ring the Amazon Basin. On the lowlands themselves correlations are scarcely conclusive. It is probable that traces of the ice age Amazon are indeed stamped on modern distributions as Simpson and Haffer suggest, yet it may still not be the most parsimonious of hypotheses to say that the past has been decisive. The way must be open to ecological hypotheses explaining the patterns of distribution from modern rainfall, modern topography and the channels of modern rivers. These hypotheses may well be the more parsimonious, at least without detailed mapping of the ancient vegetation by such means as pollen analysis, something on which no start has yet been made.

Nevertheless, it is clear that all hypotheses of the high diversity of tropical biota must now reckon with the fact that the equatorial lowlands are not immune to climatic change, being in

fact subject to environments with each northern glaciation sufficiently different to replace one biome with another. One of the most attractive of the hypotheses for high diversity has been that of Sanders (*Amer. Nat.* **102**, 243; 1968) who showed that long physical stability on ocean floors is associated with high diversity, in spite of low productivity. The suggestion that high stability in equatorial latitudes accounted for the high species list in a similar way has been attractive to many of us. We now have to modify our views. Possibly, the important part of the stability of tropical systems is still that areas must always have persisted in which seasons were minimal, because without them the biota of the wet tropics as we know them cannot have survived. The areas may have moved around a bit, but they had to be there. In these places we can still postulate lower extinction rates, higher speciation rates, or more niche-overlap as our fancy dictates. □

'robust' australopithecines and have, in fact, been placed with that group by some workers. A further problem with White and Johanson's comparative group is that they appear to have included dental measurements from Taung for teeth (4th premolars and 3rd molars) which the child did not possess (*Science op. cit.*).

White and Johanson recognise that it is the total pattern of characters which must define a taxon and set it apart from other species. While bearing this in mind, it must be pointed out that very few characters of *A. afarensis* are not also found in *A. africanus*. For example, important distinguishing features of the new species are said to occur in the anterior premolars of the mandible. In *A. afarensis* this tooth has a large outer cusp and a very small inner cusp; the long axis of the tooth is rotated 45 degrees or more to the long axis of the tooth row. Yet a similar pattern of morphology is seen in the Miocene genus *Ramapithecus* (regarded by some workers as an ancestral hominid) and is also found in the Sterkfontein specimens (Robinson *Transvaal Museum Memoirs* No. 9, 72; 1956). Similarly, the mandibular canines of *A. afarensis* are said to be large, yet in both length and breadth means this tooth is larger in the Sterkfontein sample (Robinson *op. cit.*). Other features, such as three-rooted upper premolars and an increase in molar size from front to back can also be duplicated in the South African sample. Morphological congruence, rather than distinctiveness, can also be demonstrated in the post-cranial remains. One of the wrist bones, the capitate, of *A. afarensis* is described as "waisted" and the third metacarpal, with which it articulates, is said to lack a styloid process. A capitate from Sterkfontein has a similarly constricted shape on its lateral surface (Le Gros Clark *J. Anat.* **81**, 300; 1947; Lewis, *J. Hum. Evol.* **2**, 1; 1973). Moreover, while a third metacarpal is not known from this site, the articular area on the Sterkfontein capitate may indicate that the styloid process of the metacarpal was also missing (Le Gros Clark *op. cit.*). Finally, the innominate of one member of *A. afarensis* (AL 288-1 or 'Lucy') is extremely similar in both size and morphology to one from Sterkfontein.

It is also true, however, that the *A. afarensis* specimens do show characters not known to be represented in *A. africanus*. For example, the upper central incisors are said to be very broad in the earlier group and the lateral incisors relatively small. However, the incisors are very poorly known for both *A. afarensis* and *A. africanus*. While the known central

Difficulties in the definition of new hominid species

from our Palaeoanthropology correspondent

As a group, palaeontologists have a notable tendency to propose new names for the fossils they find. Whether from scientific profundity or other motives, new binomials seem to appear with an almost greater frequency than the fossils themselves. Historically, the same has been true of human palaeontologists; proposals of five or six different binomials for the same fossil hominid are not unknown. Paradoxically, however, the enormous number of new hominid fossils that have appeared in this decade has generated very little taxonomic activity. One exception, 'Homo ergaster', has been permitted to enter an unmentioned and well-deserved obscurity.

Now, Don Johanson and Tim White have proposed a new species for the Plio-Pleistocene hominid genus, *Australopithecus* (*Kirtlandia* **28**, 1, 1978; *Science* **203**, 321; 1979). The species, *A. afarensis*, is based on specimens found at Laetoli in Tanzania and in the Hadar area of Ethiopia; they appear to date between 2.9 and 3.8 million years ago. While the majority of this material has been recovered very recently, the 'Garusi' maxilla was recovered at Laetoli in 1939 by Kohl-Larsen.

A workable definition of a fossil species continues to elude palaeontologists. While recognising, as do neontologists, that genetic isolation is the prime criterion for species formation,

the way such isolation can be recognised in the fossil record is unclear. Most definitions centre on the demonstration of morphological distinctiveness; a fossil species should therefore have a clearly defined and distinguishing set of morphological characters. This is apparently the sort of definition that Johanson and White have worked with. However, their success in demonstrating the morphological distinctiveness of *A. afarensis* is by no means clear. Their difficulty, and the difficulty of those who try to evaluate their classification, lies equally in the incompleteness of the fossil specimens and in the wide morphological variability of early (as well as recent) human populations. Moreover, the type specimen of the most appropriate comparative taxon, *Australopithecus africanus*, is a juvenile. The fact that this specimen, the Taung child, has only the first molars of its permanent dentition in place has long caused taxonomic difficulty. For this reason, the gracile australopithecines from Sterkfontein, in South Africa, are usually regarded as representatives of this species. White and Johanson have also included the australopithecines from Makapan, along with those from Sterkfontein, in their comparative group. However, the gracile status of the Makapan hominids is not certain. They do demonstrate several cranial and dental characters more often found in the heavily built

incisors are, indeed, very large in *A. afarensis* they are known from only two individuals. The comparative sample from Sterkfontein consists of a single individual. The very limited sample of lateral incisors from Sterkfontein ($n=2$ individuals) shows this tooth to be smaller than the very "reduced" *A. afarensis* tooth. In the *A. afarensis* maxilla the canine characteristically projects below the level of the other teeth and a diastema is present in the tooth row. Although this is often regarded as a primitive feature, at least one *Homo erectus* individual, from Java, also shows a similar pattern. It should be pointed out that in the original reports on the Hadar material, specimens showing these features were placed not in a primitive hominid group as they now are, but in the more advanced genus, *Homo*.

Thus, there are very few features said to be characteristic of *A. afarensis* which are, in fact, distinctive of that group. Perhaps a major feature of the specimens now grouped into *A. afarensis* is the amount of variability present. This variability originally led to the informal proposal that as many as three taxa were present at Hadar. Therefore, while the original reports maximised the taxonomic importance of this variability these current reports have, in effect, minimised it to the level of sexual dimorphism. Undoubtedly, considerable sexual dimorphism was present in hominids of the Plio-Pleistocene but can such dimorphism explain all the variability present at Hadar and Laetoli? Perhaps, but both the recovery of additional material from this important time period as well as more careful comparative studies of existing specimens are required before the validity of *A. afarensis* can be affirmed. □

Death of a schistosome

from F. E. G. Cox

Schistosoma mansoni in laboratory rodents is a useful model for the study of schistosomiasis and much of what we know about the biology of the parasites that cause the human disease has been derived from studies on rats and mice. The infection in a mammal begins when free-swimming cercariae, released from a snail intermediate host, attach to and penetrate the skin. While this is happening, the cercariae rapidly transform into schistosomula by discarding the glycocalyx required during their sojourn in freshwater and reveal-

ing the characteristic double bilayer outer membrane. Each schistosomulum then makes its way to the blood vessels, stimulating an immune response but avoiding its consequences by acquiring red cell antigens that render it immunologically invisible. However, subsequent schistosomula that have not acquired host antigens are fully susceptible to attack from the immune system and thus superinfection is effectively prevented. The schistosomulum is the obvious weak link against which any immunological attack must be directed and the development of a vaccine against schistosomiasis will depend to a large extent on our understanding of what happens to the schistosomulum during the first few hours in its host.

The immune responses against schistosomula in previously sensitised hosts are extremely rapid and effective and several effector mechanisms have been postulated including antibody and complement and complement activated through the alternative pathway. Recently, various cells have also been found to be involved, in particular macrophages in the presence of IgE (A. Capron *et al.* *Nature* **253**, 474; 1975), eosinophils in the presence of IgG (A. Capron *et al.* *Amer. J. trop. Med. Hyg.* **26**, 39; 1977; Mackenzie *et al.* *Clin. exp. Immun.* **30**, 97; 1977) and eosinophils in the presence of complement (Ramalho-Pinto, McLaren & Smithers *J. exp. Med.* **147**, 147; 1978). It is known that eosinophils adhere to a schistosomulum through either Fc receptors or complement receptors and, in *in vitro* systems, empty their contents on to the surface of the worm (McLaren, Mackenzie & Ramalho-Pinto *Clin. exp. Immun.* **30**, 105; 1977). Until now, however, the evidence that eosinophils actually kill the schistosomulum has been circumstantial: labelled chromium release, for example, is increased but no ultrastructural damage has been detected. It has now been conclusively shown by the group of workers at Mill Hill that the schistosomulum is damaged and killed (McLaren, Ramalho-Pinto & Smithers *Parasitology* **77**, 313; 1978).

The death of the schistosomulum begins when eosinophils attach to its surface, flatten out and release their contents causing a small lesion in the tegument through which the cells migrate into the interstitial tissue of the worm. The tegument is prised off and the worm dies. The actual method of attachment of the eosinophils to the surface of the worm is important as is the ratio of cells to schistosomula. 3,000–5,000 eosinophils per schistosomulum are necessary (3,000 were used

in the previous studies) and attachment through complement receptors results in 100% killing in 20 h whereas attachment through Fc receptors results in little damage within 20 h and, in some worms, no damage at all.

The eosinophil product that actually causes damage to the schistosomulum seems to be the major basic protein (MBP) from the eosinophil crystalloid core (Butterworth *et al.* *J. Immun.* **122**, 221; 1979). The destructive effects of MBP are nonspecific but schistosomulum killing is effectively specific because of the tight binding of eosinophils to antibody-coated worms and the release of MBP into a small space between the eosinophil and the schistosome surface. The action is therefore localised and no bystander host cell damage occurs.

There is now abundant evidence that eosinophils in conjunction with either IgG or complement can kill schistosomula but the whole story may be more complicated than this. Monique Capron and her colleagues at Lille have observed that both eosinophils and mast cells adhere to schistosomula and have found that, in the presence of IgG and with 5,000–10,000 effector cells per worm, the proportion of mast cells to eosinophils is a very important factor in killing (M. Capron *et al.* *Europ. J. Immun.* **8**, 127; 1978). The cytotoxic effects decrease as mast cells are depleted and increase with mast cell enrichment. Ultrastructural studies show that little damage is done to the tegument in the first 3 h but that it is very vacuolated after 20 h, findings comparable with those of the Mill Hill group. In a further series of experiments (M. Capron *et al.* *J. Immun.* **121**, 2518; 1978) it has been shown that eosinophil-dependent cytotoxicity proceeds in three steps, the activation of the mast cells, the release by these cells of a soluble mediator that acts as a signal to the eosinophils and the reception of this signal by the eosinophils. Activation of the mast cells depends on IgG binding to the schistosomulum, the IgG involved being IgG2a, the second anaphylactic antibody in rats. This antibody also seems to be involved directly in eosinophil-mediated cytotoxicity. As both mast cells and eosinophils possess receptors for IgE and complement there may be several patterns of eosinophil activation in schistosomiasis and these may act separately or together. Whether the eosinophil-complement mechanism also involves mast cells remains to be determined, for mast cells also adhere to schistosomula through complement receptors (Sher & McIntyre *J. Immun.* **119**, 722; 1977).

An understanding of the role of eosinophils in immunity to helminth infections is likely to become

F. E. G. Cox is Professor of Zoology at King's College, University of London.

creasingly important as the attachment of these cells and the release of their contents have also been seen with the adult nematodes, *Nippostrongylus brasiliensis* and *Trichinella spiralis* (McLaren, Mackenzie & Ramalho-Pinto *Clin. exp. Immun.* **30**, 105; 1977) and larval *T. spiralis* (Kazura & Grove *Nature* **274**, 588; 1978). The finding that the nematode *Ascaris suum* contains a substance that is chemotactic for eosinophils and neutrophils (Tanaka, Baba & Torisu *J. Immun.* **122**, 302; 1979) may mean that certain worms are actually instrumental in their own destruction. Immunity to helminths is complex and there are unlikely to be any simple explanations of all the facts observed so the vast amount of fundamental research being carried out is easy to justify in terms of its possible importance to our understanding of human and animal diseases.

Growing embryos *in vitro*

from Gillian Morriss

THE once inaccessible postimplantation mammalian embryo can today be grown in transparent vessels in the laboratory for various periods between implantation and an advanced stage of organogenesis. This is largely due to the work of New and his collaborators in Cambridge, and (the earliest stages) Hsu and colleagues in Baltimore (reviewed by New, *Biol. Rev.* **53**, 81; 1978). Mammalian embryologists have been slow to exploit the opportunities of whole embryo culture, but recent progress in the culture technique represents a significant increase in its potential, since the *in vitro* requirements of postimplantation mouse embryos have now been defined.

Pre and peri-implantation culture of mouse embryos are now routine procedures, whereas for postimplantation stages the techniques were previously well worked out only for the rat. Rat embryo culture is an important technique for the investigation of environmental factors such as energy supply, gas phase constituents, and chemical teratogens. For specific chemical interference with intra or extracellular components such as basement membrane collagen, glycosaminoglycans and microfilaments, it is immaterial which mammalian species is used. However, for the investigation of abnormal development which is genetic in origin,

mouse mutants provide a range of abnormalities unrivalled by any other experimental species. These mutants represent an important potential source of information on normal and abnormal mechanisms of mammalian morphogenesis. The onset of abnormal development of several of them occurs during the early postimplantation period (primitive streak stage to mid-organogenesis), and *in vitro* studies will make an important contribution to elucidation of the mechanisms involved.

Y.-C. Hsu (*Devl Biol.* **68**, 453; 1979) has achieved a significant improvement in the proportion of preimplantation stage mouse embryos which attach *in vitro*, develop into 'egg cylinders' and subsequently reach the 5–10-somite stage. The technical alterations were simple: blastocysts were cultured singly in 2 ml medium in 35 mm culture dishes, and 2 days after attachment (early 'egg cylinder' stage) the serum component in the medium was changed from 20% fetal calf serum to 20% human cord serum (the synthetic component was CRML 1066 throughout). Twelve out of twenty embryos developed to the 5 to 10 somite stage, after which they began to degenerate. It is important to note that the photographs of these 'successful' embryos closely resemble rat embryos grown at this stage in dish cultures: the spinal neural tube closes, but the cranial neural folds fail to change from their early convex shape to the concave shape which precedes closure of the brain tube.

From the primitive streak stage onwards, rat embryos undergo normal morphogenesis only when the culture vessel and/or the culture medium is continuously moving. T. W. Sadler (*J. Embryol. exp. Morph.* **49**, 17; 1979) has modified this technique for the culture of mouse embryos from the 2–4-somite stage for up to 48 h. During this period mouse embryos require a greater volume of gas phase than rat embryos; however, their liquid requirements are apparently identical, with rat serum supporting normal development. Successful culture of younger mouse embryos, from the primitive streak stage for 48 h, has been achieved by M. Snow and P. P. L. Tam (personal communication), using 30% newborn calf serum in Dulbecco's modified Eagle's medium supplemented with glucose (4.5 g l^{-1}).

Meanwhile, the better-established techniques of rat embryo culture are yielding information on the metabolic requirements of the early embryo, and on some aspects of the relationship between these and morphogenesis. Klein *et al.* (*J. exp. Zool.* **203**, 313; 1978) have improved development of 10-day embryos in small quantities of serum (four embryos per 2 ml) by changing the serum after 24 h. The im-

provement was related to depletion of a protein (or proteins) of approximately 125,000 molecular weight; this protein may be identical to the α_2 -globulin of 126,000 molecular weight, identified by Hoch and McVey (*J. biol. Chem.* **252**, 1881; 1977) as one of the two major human serum DNA-binding proteins.

Energy production of 10-d embryos is primarily through anaerobic glycolysis (Tanimura & Shepard *Proc. Soc. exp. Med. Biol.* **135**, 51; 1970); subsequently (day 10 to day 12) oxygen dependence progressively increases, as the yolk sac and then the chorioallantoic placental circulations develop. Not surprisingly, these observations are matched by the oxygen requirements of cultured embryos (reviewed by New *op. cit.*). Robkin and Cockcroft (*Teratology* **18**, 337; 1978) have compared the effects of oxygen deprivation and carbon monoxide elevation on cultured 11–12-d embryos. Decreased availability of oxygen produced a greater response (depression of metabolism and growth rate) than elevated carbon monoxide, and the authors suggest that at this stage of development oxygen transport is primarily through solution rather than in combination with haemoglobin.

Our understanding of the mechanisms involved in controlling most aspects of normal and abnormal organogenesis has progressed very little compared with progress in other areas of developmental biology during the past decade or so. It is to be hoped that the recent improvements in techniques of mammalian embryo culture will soon be fully utilised in pursuit of such studies. □

A hundred years ago

ON Tuesday morning, in the presence of a small number of his sorrowing friends, the remains of the late Prof. W. K. Clifford were placed in their last resting-place in Highgate Cemetery.

THE following grants have lately been made from the Research Fund of the Chemical Society: —10*l.* to Dr. C. A. Burghardt for an investigation into the constitution of topaz; 20*l.* to Mr. Francis Jones for the investigation of boron hydride; 15*l.* to Mr. F. D. Brown for the study of the theory of fractional distillation; 30*l.* to Dr. Dupré for the estimation of organic carbon in air; and 15*l.* to Prof. T. E. Thorpe for the investigation of albitene, the hydrocarbon of nut-pine.

The new frontier of particle physics

John Mulvey

University of Oxford, Department of Nuclear Physics, Keble Road, Oxford, UK

Quarks and leptons have emerged as elementary constituents of matter. To these may perhaps be added the field particles, or mediating agents, of a unified theory of the weak and electromagnetic forces and also those of a new theory of the strong (nuclear) force. This article briefly outlines some of the main items of evidence for this new picture and indicates a few of the many crucial questions to be answered.

THE first lepton to be discovered was the electron, by J. J. Thompson in 1897. The leptons are a family of particles with spin 1/2 (in units of $\hbar$) and a membership summarised in Table 1 which includes two recent additions.

The charged leptons participate in both the electromagnetic and the weak interaction (responsible for processes such as radioactive β -decay) while the neutrinos, with zero electric charge, are influenced only by the weak force.

Since its discovery 40 years ago, the muon has remained one of the great enigmas of particle physics; it differs from the electron only in mass, has equal strength couplings to the electromagnetic and weak forces and shows no sign of additional modes of interaction which might account for this mass difference. Moreover, in 1961 the electron and muon were found to be associated with different neutrinos, ν_e and ν_μ . Another lepton pair has now been added to the list; with the matching expansion in the numbers of types of quarks this multiplicity of forms is one of the most tantalising aspects of particle physics at present.

The annihilation of high energy electrons (e^-) and positrons (e^+) brought together in the head-on collision of oppositely circulating beams of e^- and e^+ can lead to the creation of charged lepton pairs or numbers of hadrons (particles which participate in the strong interaction as well as in the weak and electromagnetic interactions). The τ -lepton was discovered in 1975 by Perl *et al.*¹ using the e^+e^- machine SPEAR built at the SLAC laboratory. Its existence has been confirmed by experiments² at the similar machine, DORIS, at the DESY Laboratory, Hamburg. It is almost certainly associated with a new neutrino, ν_τ , and although the mass limits on ν_τ are still high it is for the moment assumed, like ν_e and ν_μ , to have zero mass.

The magnetic moments of the electron and muon have been measured to remarkable precision in two experiments of great

technical ingenuity and scientific elegance. The work on the electron, by Dehmelt *et al.*^{3,4} at Seattle has reached an accuracy of 1 part in 10^{10} and at CERN the group led by Picasso⁵ has achieved 1 part in 10^8 for this static property of the unstable muon. These experiments test the validity of quantum electrodynamics (QED), the quantised electromagnetic theory; they also probe the structure of the particles and the possibility of couplings to additional fields of force. Dirac's theory for point-like particles of spin 1/2 predicts a magnetic moment of $\mu_D = eh/2mc$ (m is the particle mass), however, the measured values are very slightly higher (by about 1 part in 10^3) and the difference is called the anomalous magnetic moment. In QED the anomalous moment is due to corrections to μ_D , called radiative corrections, which arise from interactions of the charge with the electromagnetic field; these can be illustrated by the

Fig. 1 Feynman diagrams showing contributions to the magnetic moment of the electron.

Feynman diagrams of Fig. 1. (Feynman diagrams illustrate details of the interactions between particles and fields by showing their evolution in space and time; with a set of rules given by Feynman they provide a prescription for calculating transition rates. One space dimension is shown and time 'flows' from left to right.)

The lowest order diagram corresponds to interaction with a virtual photon, mediator of the external electromagnetic field, and gives the Dirac moment, μ_D ; the radiative corrections involve emission and re-absorption of virtual photons, including in higher orders the transient presence of virtual charged lepton pairs. This 'structure' associated with the field is the source of the anomalous moment. The calculations have been carried out to sixth order (96 diagrams contribute) and the excellent agreement between theory and experiment^{6,7} represents a remarkable success for QED. In addition the experiments led to the following conclusions about the electron and muon

Table 1 The leptons (and anti-leptons)

Name		Charge*	Mass (MeV)†	Lifetime
Electron	$e^-(e^+)$	$-1(+1)$	0.51	Stable
Electron-neutrino	$\nu_e(\bar{\nu}_e)$	0	$0(<4 \times 10^{-5})$	Stable
Muon	$\mu^-(\mu^+)$	$-1(+1)$	105.7	2.2×10^{-6} s
Muon-neutrino	$\nu_\mu(\bar{\nu}_\mu)$	0	$0(<0.5)$	Stable
τ -lepton	$\tau^-(\tau^+)$	$-1(+1)$	1807	$<3 \times 10^{-12}$ s
τ -neutrino	$\nu_\tau(\bar{\nu}_\tau)$	0	$0(<300)$	Stable(?)

*In units of the electron charge, e .

†The proton mass in these units is 938.3. The neutrinos are assumed to have zero mass; the present experimental limits are given in parentheses.

there is no evidence of a new coupling sufficient to account for the heavier mass of the muon; (2) the electron and muon behave like point-like, structureless particles at least down to distances approaching 10^{-15} cm.

The quarks

Leptons can be created and their properties measured to very high precision in the laboratory. In contrast all we know about quarks has to be inferred from indirect information like the patterns of hadron spectroscopy, the products of e^-e^+ annihilation, the scattering of leptons probing the nucleon and similar processes. This is a severe technical difficulty, and the failure to establish the existence of free quarks has cast doubt on this concept. These difficulties make it worth summarising some of the evidence which has led to the present common acceptance of the quarks as constituents of the hadrons.

The quark proposal^{8,9}, made by Gell-Mann and independently by Zweig in 1964, was the culmination of a successful attempt to explain the numerous spectrum of hadronic states (more than 200 are known). There are two main classes of hadrons: the baryons have half-integer spin and include the proton and neutron (nucleon); the mesons have integer spin. (All particles of half-integer spin are called fermions and those of integer spin are called bosons.)

When the quark model was proposed only three components were required to 'build' all the known hadronic states; these were the u, d and s quarks listed in Table 2. The u and d quarks form an isospin doublet (like the proton and neutron), while the s quark carries the attribute of strangeness, a hadronic property discovered in the late 1940s. The different quark types have been given the collective name 'flavours'. Quarks not only have the exotic property of fractional electric charge, which should make them easily recognisable if freed from hadronic confinement, but also baryon-number (B) of $1/3$ ($-1/3$ for $\bar{q}$). Baryon-number $+1$ is assigned to all baryons (-1 to anti-baryons) and 0 to all mesons; it is a quantity believed to be strictly conserved by all interactions, leading to the apparently absolute stability of the lightest baryon, the proton.

The baryons are formed from three quarks ($3q$) and the mesons from quark-antiquark pairs ($q\bar{q}$); examples are: proton (uud), neutron (udd), π^+ -meson ($u\bar{d}$) and K^+ -meson ($u\bar{s}$). The ($3q$) and ($q\bar{q}$) recipe assembles multiplets of states, all with the same spin and parity; the multiplets formed from the u, d and s quarks correspond to those representations of the unitary symmetry group $SU(3)$ which are just the ones needed to accommodate the states observed (at least up to a mass of 3 GeV). The quark triplet corresponds to the simplest (non-trivial) representation of $SU(3)$. Baryons ($3q$) form multiplets of dimension (number of members) (1), (8) and (10) while the mesons ($q\bar{q}$) occur in (1) and (8).

Invariance to transformations of the $SU(3)$ group would imply equal mass for all the members of a multiplet. However, this symmetry is broken to the extent that mass differences occur; one may accommodate these by making the s-quark ~ 150 MeV heavier than the u and d quarks. The masses and magnetic moments of the low mass hadrons can be understood if the quarks have spin $1/2$, have Dirac-like moments and if the effective masses of the u and d quarks are ~ 350 MeV. (But these should not be taken as the masses free quarks might have—if they exist.)

Table 2 Quarks and anti-quarks

Name (Flavour)	Charges			
	q		$\bar{q}$	
	$+2/3$	$-1/3$	$-2/3$	$+1/3$
Up	u		$\bar{u}$	
Down		d		$\bar{d}$
Charm	c		$\bar{c}$	
Strange		s		$\bar{s}$
[Top?]	[t]		[$\bar{t}$]	
Bottom		b		$\bar{b}$

Fig. 2 Production of Y and Y' in e^+e^- annihilation at DORIS¹⁹.

Giving the quarks spin $1/2$ permits a description of hadron states embracing $SU(3)$ multiplets of different spin, within representations of the higher symmetry $SU(6)$. The quark model has been extended by including orbital (angular momentum) and radial excitations to account for higher mass and spin regions of the spectrum.

The original triplet of quarks had to be extended to a quartet (and thus $SU(3) \rightarrow SU(4)$) by the discovery of a new hadronic flavour, charm (c), in 1974. This was first signalled by the observation of a heavy, surprisingly stable meson state of mass 3.1 GeV called the J/ψ found simultaneously by the groups led by Ting¹⁰ at Brookhaven and Richter¹¹ at SPEAR. The J/ψ is formed of ($\bar{c}c$) and is accompanied by a number of other 'charmonium'^{12,13} states in a spectrum typical of that expected for a two fermion system (analogous to positronium, e^+e^-). The existence of a fourth type of quark with charge $+2/3$ had been suggested earlier by Glashow (who chose the name) and his collaborators; at first this was to achieve a quark-lepton symmetry (two pairs of each) and then¹⁴ to explain why a strangeness changing neutral-current decay mode of the K^0 -meson ($K^0 \rightarrow \mu^+ + \mu^-$) was strongly suppressed.

A fifth quark, named 'bottom' (b), (or 'beauty') is required by the experiments¹⁵ of Lederman *et al.*; this almost certainly heralds the existence of a sixth quark with a new flavour, to be called 'top' (t) (or 'truth'). Lederman's experiment¹⁶ detected a new meson state, called the Y (upsilon), as a peak at 9.5 GeV in the mass spectrum of ($\mu^+\mu^-$) pairs produced by 400 GeV protons at Fermilab. The same state has since been found^{17,18} at the DORIS e^+e^- colliding beam machine, running close to its upper limit of energy, and in pp collisions at the CERN ISR. The upsilon is partnered by at least one higher level, Y' (see Fig. 2)¹⁹ and probably a second, making a heavy analogue of the charmonium spectrum; this time the states are of hidden bottom ($b\bar{b}$) rather than hidden charm ($c\bar{c}$). The evidence points to charge $-1/3$ for this massive, ~ 5 GeV, quark and the new higher energy e^+e^- machine, PETRA, just starting to operate at DESY will be able to make states containing a single b-quark (such as, ($b\bar{d}$), and ($u\bar{b}$)).

The pattern of quark flavours, pairs of charge $-1/3$ and $+2/3$, demonstrated by the first four, is related to a quark-lepton symmetry embedded in the new unified theory of the weak and electromagnetic interactions. This is the reason for anticipating the sixth flavour, top, to partner bottom. It is not possible to predict the mass of hadrons carrying the t-quark but 'toponium' and 'exposed top' hadrons probably lie within reach of PETRA and another new e^+e^- machine called PEP, due to start up at SLAC in a year or so, both with maximum energies in the 40 GeV region.

Another important property of quark states, called 'colour', has emerged from the study of hadron spectroscopy. Certain baryons (such as the Δ^{++} state of mass 1238 MeV and spin $3/2$) contain three identical quarks with parallel spins in a state which is symmetric (the wave function does not change sign) to the

interchange of a pair of quarks. This breaks a cardinal rule, the spin-statistics theorem of Pauli, which requires the overall wave-function describing a system of identical fermions to be anti-symmetric on interchange of a pair. The difficulty has been resolved by introducing another degree of freedom²⁰, a means to distinguish the otherwise identical quarks. This requires a set of three labels say, red, blue and green. Then the forces between quarks are required to be such that at any instant each quark is a different colour (for example, the $\Delta^{++}(1238)$ state is $(u_R u_B u_G)$). The requirement that the colour part of the wave function be anti-symmetric to interchange of a pair of colour indices (to satisfy the spin-statistics rule) limits the low-lying hadron states to colour singlets—that is, states with no net colour; thus this new factor need not lead to a further great expansion of the hadron spectrum through the existence of coloured states.

Alternatively, by postulating that only colour singlet states may exist the possible quark combinations are reduced to just $(3q)$ and $(q\bar{q})$ so explaining the absence of free quarks (q), or such systems as (qq) , $(q\bar{q}q)$, and (qqq) . (But quark 'molecules' such as $(q\bar{q}-q\bar{q})$ or $(qqq-q\bar{q})$ would be allowed and there is some tentative evidence for them).

The lifetime of the π^0 -meson provides one direct piece of evidence for colour: without it the prediction of the lifetime is wrong by a factor of 9. Colour is evidently closely related to the nature of the quark binding force, a point we shall discuss with the new theory of the strong interaction. But we now look at three different types of experiment giving evidence for the constituent quark model and further support for colour.

Lepton-nucleon scattering

Although experiments at the highest possible energies have failed to detect quarks knocked out of the nucleon, they have, nevertheless, played an essential part in creating the presently accepted picture of hadron structure. This is particularly true of the use of leptons as high energy probes of the nucleon; they are, apparently, structureless themselves and the nature of the interaction, electromagnetic for electron and muon, weak for the neutrino, is well understood.

The electron scattering experiments at SLAC late in the 1960s, and those soon afterwards in the Gargamelle bubble chamber at CERN, Geneva, using beams of neutrinos, repeated for the nucleon what Rutherford's α -particle scattering experiments did for the atom early this century (for a review see ref. 21). They found evidence that high momentum transfer collisions occurred with point-like constituents within the nucleon; moreover, the two experiments together showed that these constituents (or partons as Feynman named them) possessed just the properties expected of quarks: fractional electric charge and spin $1/2$. Furthermore, although subject to rather large errors, the neutrino experiment can 'count' the number of 'valence quarks' in the nucleon (those determining its physical attributes) and the result is close to three.

There was a significant additional observation, the quarks (plus a small component of $(q\bar{q})$ pairs forming a 'sea') only carry ~50% of the nucleon momentum. This forced the conclusion that the remaining 50% is carried by other constituents which display no electromagnetic or weak interaction; the obvious

speculation was that these other constituents must be associated with the strong force binding the quarks and so they were called 'gluons'. In the quark-parton mode, of lepton-nucleon scattering the elementary interaction with the quark can be represented by Fig. 3a and b for the electron (or muon) and neutrino cases respectively. The struck quarks do not escape as nucleon debris so it must be supposed that in some subsequent strong interaction between the quarks and gluons the quark is 'dressed' and what emerges is a jet of conventional hadrons. Nevertheless, in some average sense this jet is expected to carry information about its parent quark.

This simple point-like behaviour which implies no dependence on a fundamental length or scale and in which the quarks are treated as free, independent entities is often referred to as scaling; it leads to a linear rise with energy of the weak interaction total cross-sections. However, further experiments with electrons at SLAC, muons and neutrinos at Fermilab and recently with large detectors exposed to the high energy neutrino beams of the CERN-SPS, have revealed departures from this simple picture. This is no surprise. The linear rise must be halted before the cross-section reaches an upper bound set by reaction theory, the unitarity limit; a damping of the rise sets in when momentum transfers become comparable with the mass of the mediators of the weak interaction, but these effects are not significant in the present experiments. There is also the apparent paradox in a picture of quarks so strongly bound they cannot escape yet act quasi-free under the impulse of a high momentum transfer collision. In fact these 'scale-violating' effects, occurring at the 10–20% level, may prove to be important clues to an understanding of the interaction between quarks and gluons, now seen as the basic form of the strong interaction.

Electron-positron annihilation

The creation of lepton pairs or hadrons in the annihilation of high-energy electrons and positrons takes place through an intermediate virtual photon and there is good evidence that in hadron production the second step is creation of a $(q\bar{q})$ pair, (see Fig. 4b). There are three kinds of evidence for the quark mechanism.

First, the strength of the electromagnetic coupling to the virtual photon is proportional to electric charge and this leads to a prediction of the ratio of hadron production (via quarks) to that of muon pairs:

$$R = \frac{\text{rate to hadrons}}{\text{rate to } \mu^+ \mu^-} = 3 \sum_j e_j^2$$

where e_j is the charge of the quark of flavour j , and the 3 is due to the three quark colours. At total annihilation energies ~2.5 GeV, where the u , d and s quarks should contribute, the value of R is ~2.5, quite close to $3[(1/3)^2 + (1/3)^2 + (2/3)^2] = 2$ which is the simple quark model prediction. Note that, for fractional charges, agreement requires the colour factor of 3, otherwise the prediction would be $2/3$. At energies ~5 GeV, above the threshold for production of charmed hadrons and the τ -lepton, R has risen to 4.7 ± 0.05^{22} again in reasonable agreement with the new expected value of 4.33 (1 is added by the τ -lepton and 1.33 by charm.)

A second observation^{23,24} is that the hadrons tend to emerge in two 'back-to-back' jets, presumably the progeny of the intermediate $(q\bar{q})$ pair; this effect is particularly clear at high total energies, above 5 GeV, where the angular spread in each jet is less broad. A remarkable confirmation of this comes from the angular distribution in the angle made by the axis of these two jets, with respect to the line of the e^+e^- collision; this is exactly as predicted for quarks of spin $1/2$.

Muon-pair production by hadrons

The quark-parton model is also successful in describing the creation of pairs of muons in high energy collisions between hadrons.

The mechanism proposed by Drell and Yan²⁵ is shown in Fig. 5: it is assumed that in the collision an anti-quark of the $(q\bar{q})$ sea

Fig. 3 a, Electromagnetic—photon exchange. b, Weak—vector boson (W^+) exchange.

Fig. 4 a, Lepton pair production. b, Hadron production.

in one hadron annihilates with a quark in the other hadron resulting in the creation of a lepton pair. This is like a reversal of the e^+e^- annihilation to hadrons (Fig. 4b) and the probability of making muon pairs of a certain mass can be written as a product of the rate for the $(q\bar{q})$ annihilation to leptons and the probability of finding a q and $\bar{q}$ carrying given fractions of the hadron momenta. The first quantity is calculable, and already tested by the e^+e^- annihilation experiments, while the second can be related to the high energy lepton scattering experiments.

The distribution in mass of muon pairs created by 400 GeV protons at Fermilab in the experiment of Lederman^{26,27} is shown in Fig. 6. The continuum (away from the Υ region) is well described by the Drell-Yan model using q and $\bar{q}$ momentum fraction distributions for the nucleon which are quite compatible with those deduced from lepton scattering; the comparison also favours the colour factor of 3. Muon pair production provides a means of sampling the $\bar{q}$ of the sea and also the valence q and $\bar{q}$ of mesons when these are used as incident hadrons.

Thus three quite different types of experiment reflect the same internal structure and taken together with hadron spectroscopy (and a number of other phenomena not mentioned) the total body of evidence in favour of quark constituents is now overwhelming. (For recent reviews see refs 28,29.) But there are significant discrepancies, quantitative and qualitative, which show that the naïve quark-parton model is not the whole story. The next stage must be to see if these discrepancies also have a common origin, in particular, whether they are reflections of the quark-gluon interaction.

Weak and electromagnetic interactions

Like the electromagnetic force the weak interaction is believed to be mediated by spin 1 particles, called intermediate vector bosons (Table 3) which must be massive (>20 GeV) because at present energies there is no significant damping of the energy dependence of the cross section. The weak interaction responsible for β -decay, and many other processes, is well described by the V-A theory in which two forms of vector interaction (V and A) participate. This mixing of V and A causes the parity violation, or lack of invariance with respect to transformations between mirror-image situations, which is characteristic of the weak interaction.

The law of conservation of electric charge can be linked to the fact that the electromagnetic field potential is not unique or,

Fig. 5 Drell-Yan mechanism for $\mu^+\mu^-$ pair production in nucleon-nucleon collision.

Fig. 6 The mass distribution of $\mu^+\mu^-$ pairs produced by 400 GeV protons at Fermilab^{26,27}.

equivalently, that the theory, QED, is invariant to transformations, called gauge transformations, of the unitary group U(1). The electromagnetic interaction does not violate parity. Nevertheless, the vector nature of both forces made it natural to seek a theoretical framework, a gauge theory³⁰, able to describe both phenomena. However, there seemed to be at least one fundamental obstacle: the only known form of the weak interaction involved a change of charge by the participants, requiring the exchanged field particle to carry electric charge. In contrast the electromagnetic exchange current is neutral and seemed to have no counterpart in the weak interaction. Most unification schemes called for neutral as well as the familiar charged weak current.

This crucial question was settled at CERN in 1973 by the discovery of weak neutral current interactions in an experiment made by Lagarrigue and his collaborators^{31,32} using the Gargamelle bubble chamber exposed to the CERN neutrino beam. The most successful unified gauge theory is also the simplest; it is due, independently, to Salam and Weinberg³³⁻³⁵ and owes its firm theoretical foundation to the work of 't Hooft^{36,37}. Experimental support has now been assembled for this theory in various neutrino experiments and also, very recently, by an elegant experiment³⁸ carried out by Taylor *et al.* at SLAC in which minute parity violating effects due to the weak neutral current have been observed in the scattering of polarised electrons by deuterium. This provides the first test of the Salam-Weinberg theory outside neutrino induced processes and the result is in excellent agreement with those from the neutrino experiments. Attempts have been made to detect parity violation due to weak neutral current effects in certain atomic transitions and after some early null results parity violating effects have now been observed; however, the experiments are difficult and the situation remains unclear.

The Salam-Weinberg theory is a gauge theory in which the intermediate vector bosons couple to left-handed doublets (Table 4) of the quarks or leptons (or to right-handed doublets of anti-quarks or anti-leptons). (Left-handed and right-handed

describe the correlation between spin and momentum directions. A right-handed particle moves in the direction which also corresponds to a clockwise twist—like a right-handed corkscrew. The asymmetry in couplings is clearly parity-violating.) The charged current interaction, mediated by a W^+ , transforms one member of a doublet into the other, like a rotation in a 'weak isospin' space. These operations are those of an $SU(2)$ gauge transformation group; thus the basic gauge symmetry structure of the theory is $SU(2)_W \times U(1)_E$.

Actually the charge $-1/3$ members of the weak $SU(2)$ doublets are not identical with the flavour states d and s of hadron spectroscopy. The weak interaction couples to a mixture of s and d ;

$$d' = d \cos \theta_c + s \sin \theta_c \quad s' = -d \sin \theta_c + s \cos \theta_c$$

where θ_c is the mixing angle, introduced by Cabibbo³⁹. (Any mixing with b is small.) This structure explains the depressed rates of decay of strange particles ($s \rightarrow u$ is proportional to $\sin^2 \theta_c \sim 0.06$) and also provides the mechanism involving the charm quark proposed by Glashow, Illiopolous and Maiani⁴⁰ to explain the extremely low rate of $K^0 \rightarrow \mu^+ \mu^-$ decay.

Table 3 The mediators

Force	Name	Mediators Mass (GeV)	Spin	State of theory
Gravity	Graviton	0	2	Quantised theory not established.
Weak +	Intermediate Vector Bosons	$W^\pm$ (~ 78) Z^0 (~ 89)	1 (V-A) —	Unified gauge theory $SU(2)_W \times U(1)$
Electromagnetic	Photon	γ 0	1	QED Salam-Weinberg almost established.
Strong	Gluon	g 0	1	QCD Attractive new gauge theory; some support but not established.

A condition which must be satisfied to ensure that unmanageable infinities do not prevent calculations with the theory takes the form, in the Salam-Weinberg case, of the requirement that the sum over the charges of the quark and lepton doublets must be zero. Table 4 shows this condition is satisfied provided there are three colours and the numbers of lepton and quark pairs are equal.

The success of the Salam-Weinberg theory is especially remarkable as it contains only one free parameter, the Weinberg angle, θ_w , which measures the relative strengths of the electromagnetic (e) and weak (g) interactions:

$$\sin^2 \theta_w = e^2 / g^2$$

$\sin^2 \theta_w$ has been determined in various experiments, including the one on electron-deuteron scattering at SLAC, and all the values obtained are close to the average, 0.23 ± 0.02 . One prediction of the theory gives the masses of the weak vector bosons; these are:

$$M(W^\pm) = \frac{37.3}{\sin \theta_w} \text{ GeV} \sim 80 \text{ GeV}$$

and

$$M(Z^0) = \frac{M(W)}{\cos \theta_w} \sim 90 \text{ GeV}$$

No existing particle accelerator or colliding beam machine can reach the energies needed to create these states which thus present a major challenge for the next generation of super high energy devices. The first such opportunity will come from the proton-anti-proton collider⁴⁰ now under construction at

CERN. The aim is to store both protons and anti-protons in the CERN SPS; the two beams will circulate in opposite directions at an energy of 270 GeV so that when they are made to collide in the centre of the detecting apparatus 540 GeV will be available for the creation of W s and Z^0 s.

Table 4 Weak $SU(2)$ doublets

Charge	Quarks	Leptons	Charge
+2/3	$\begin{pmatrix} u \\ d' \end{pmatrix}_L$	$\begin{pmatrix} \nu_e \\ e^- \end{pmatrix}_L$	0
-1/3	$\begin{pmatrix} c \\ s' \end{pmatrix}_L$	$\begin{pmatrix} \nu_\mu \\ \mu^- \end{pmatrix}_L$	-1

A theory for the strong interaction

A gauge theory of the strong interaction in its most elementary form, the binding of quarks in their hadrons, has been developed based on the idea that colour is the 'strong charge' and the force between quarks is mediated by the exchange of coloured, zero mass gluons. The gluons form a colour octet, (8), of spin 1 and the $SU(3)_c$ symmetry of colour is supposed to be exact. This theory, known as quantum chromodynamics or QCD^{41,42}, generates a force with two remarkable properties which provide a plausible basis for understanding the paradoxical behaviour of quarks and the theory is now receiving more quantitative support from experiment.

In contrast to QED, where the exchange particle carries no charge and so photons do not interact with each other (at least in lowest order), in QCD the gluons carry colour-charge and can interact strongly. This leads to a profound difference in the forces: whereas the Coulomb potential between electric charges falls at large distances ($\propto 1/r$), in QCD the force between quarks may increase; conversely the force becomes weaker at small distances, such as are probed in high momentum transfer collisions. The latter property, known as asymptotic freedom, provides a qualitative basis for understanding the success of the simple quark-parton model. On the other hand, the increase at large quark separations may be sufficient to prevent free quarks escaping from their confinement within the hadrons; instead the increase in field energy may be released in the form of created ($q\bar{q}$) pairs, or mesons. This can be visualised as shown in Fig. 7. The high momentum W imparts an impulse to the 'almost free' quark q ; as q moves away the binding force increases, eventually the stored energy is more than sufficient to create a new ($q\bar{q}$) pair. In effect, the 'spring' breaks, a new hadron is created, the quarks remain confined. Like the quarks the coloured gluons are also permanently imprisoned.

The large distance behaviour, where the quark-gluon coupling is strong, is not, so far, amenable to calculation except in a strongly model-dependent way. However, considerable success has been achieved in constructing models including quark confinement and describing the spectroscopy of hadron states^{21,30}. On the other hand, a perturbation method of calculation can be applied in the small distance, high energy regime where the coupling strength is weaker. This permits, for example, the calculation of 'strong radiative corrections' to the quark-parton model. As already described, the naïve version assumes the quarks are free but the first order effects of gluon coupling lead to departures from exact scaling which are calculable and so can be compared with those found by experiment.

Fig. 7 Illustration of quark confinement mechanism.

These corrections are shown by examples of first order QCD processes in Fig. 8. Recent analyses of experimental data on scaling violations show good agreement on the whole with the QCD predictions. One example is the case of neutrino scattering studied by Perkins and collaborators using the BEBC and Gargamelle bubble chambers in the CERN neutrino beams. Scaling violation is demonstrated^{44,45} in this experiment by the dependence of moments of the observed quark momentum-fraction distribution in the nucleon on the momentum transfer in the collision. The results obtained are shown in Fig. 9 as plots of three different pairs of moments; the lines in this figure have slopes predicted by QCD which are in good agreement with the data. This result demonstrates that the form of the scaling violation is consistent with that predicted by QCD but more particularly the magnitude of the slopes is evidence for the vector nature of the gluon.

Fig. 8 Examples of 1st order QCD processes.

The first order QCD correction (see Fig. 8b) may also account for the measured values of R being rather larger than the naïve prediction. More direct evidence for gluons is being sought among the showers of hadrons created in high energy collisions, some of which should be born in gluon jets. The heavy-onium states, like charmonium or bottomonium, formed by e^+e^- annihilation are constrained to decay to hadrons through three gluons ($Y \rightarrow 3g \rightarrow \text{hadrons}$) so providing another 'laboratory' for gluon studies. So far a clear difference has been established between hadron production through Y formation and direct e^+e^- annihilation, but a proof of the intermediate role of three gluons may have to wait for the higher mass toponium.

Many other experiments are now bringing QCD under scrutiny and the present indications are that we may have, for the first time, a serious contender for a theory of the strong interaction.

Questions for tomorrow

On the experimental front further results from the polarised electron scattering experiment at SLAC may soon close (or open) one of the few remaining loop-holes left for an alternative to the Salam-Weinberg unified theory of the electro-weak interaction, a synthesis of significance equal to Maxwell's unification of the electric and magnetic forces. But the crucial tests must await the observation of the intermediate vector bosons, W^+ and Z^0 . These may be identified at the high energy colliders under construction like the CERN $\bar{p}p$ facility due to operate in 1981 using the SPS ring or the 400 GeV proton-proton collider, ISABELLE, at Brookhaven which is planned to be ready in 1986. Another contender will be the $\bar{p}p$ collider planned at Fermilab using the superconducting magnet ring being installed to double the present accelerator's energy to 1,000 GeV; this may eventually allow 2,000 GeV to be reached in the collision. However, a full study of their properties and decisive tests of the unified gauge theory through study of the

process $e^+e^- \rightarrow W^+W^-$ will need a super high energy e^+e^- collider such as the large electron positron (LEP) machine⁴⁶ now under discussion in Europe which could have an energy of up to 100 GeV in each beam.

The almost conclusive experimental support for the Salam-Weinberg theory brings another question to the fore. It is based on a gauge theory, due to Yang and Mills⁴⁷, which only applies to massless particles. The introduction of mass depends on a device called the Higgs mechanism and a consequence is the existence of at least one neutral, spin 0, particle called a Higgs meson. Its general properties are known but the mass is not predicted, it must be greater than ~ 12 GeV but may be as heavy as 1,000 GeV. The search for the Higgs meson, or at least an indirect hint of its existence, must be one of the prime objectives for the future and especially for a LEP.

The programme seems well defined, but suppose that there are no W^+ or Z^0 to be found? At the high energies of a LEP the strength of the weak interaction will overtake that of the electromagnetic force and a new view of their character is bound to be revealed.

In the field of strong interactions QCD has brought new hope of reaching and understanding although daunting problems remain, especially in the 'large distance, low energy and strong coupling' regime where the problem of quark confinement remains to be understood. Great efforts are being applied to making tests in the 'short distance' regime probed in high energy processes and for which calculations using perturbation methods can be attempted. QCD has great theoretical attraction, being a gauge theory with vector mediators it carries the promise of eventual unification with the electro-weak theory, but decisive experimental tests are going to be very difficult. The principal actors, quarks and gluons, move on a stage hidden from direct observation.

Remembering the sequence atom, nucleus, nucleon, the frontier has now moved inside the nucleon; but the old hadron spectroscopy seems to have been replaced by a new spectroscopy of quarks and leptons. How many flavours of quarks and leptons are there and is there an even deeper layer of structure to be unravelled? Only experiments can show; still more flavours may be discovered at PETRA, PEP and LEP. However, one significant sign may be the growing connection between the elementary particle states (quarks and leptons) and the character of the forces. The Salam-Weinberg theory links the quarks and the leptons; QCD loses its property of asymptotic freedom if there are more than 16 quark flavours; the

Fig. 9 Data from neutrino scattering experiment at CERN^{44,45}. The scale violating dependence on momentum transfer squared (q^2) spreads the points; the lines shown have the slopes predicted for spin 1 gluons (full-line) or spin 0 gluons (dashed line).

increase from 4 to 6 quarks is just what is wanted⁴⁸ to provide a mechanism for the violation of time-reversal invariance observed in rare decays of the K^0 -meson.

A fundamental challenge is the search for a theoretical structure which would unify the three forces within one strong-electro-weak theory. This requires a larger gauge symmetry including $SU(3)_c \times SU(2)_w \times U(1)_E$. Such a grand unification may provide answers to many outstanding questions including the relative masses of the quarks and leptons, the values of $\sin^2 \theta_w$ and the Cabibbo angle, θ_c . In these schemes the proton usually loses its absolute stability, decaying with a lifetime which may be as short as 10^{34} yr; the present limit is $>10^{30}$ yr. Beyond this lies the still greater task, left by Einstein, of achieving a unification

with gravity, the force which moulds the Universe but which is too weak for its effects to be studied at the particle level.

Most of the quarks and leptons seem superfluous; the enigma of the muon has only deepened as its new companions have arrived. To construct our world, outside the high energy physics laboratories, Nature needs only one quark pair (u,d) and one pair of leptons (ν_e, e^-). The other flavours of quarks and leptons seem to play no essential role (except perhaps the extra neutrinos which (if massless) may have helped to determine the course of the first few moments⁵⁰ following the Big Bang); they are clues to the overall scheme of Nature, which, in Salam's view, may be more sparing of principles than of particles.

Radiocarbon measurements on submerged forest floating chronologies

J. A. Campbell* & M. S. Baxter

Department of Chemistry, The University, Glasgow, UK

The submerged forests along the west coast of England and Wales provide a unique source of wood for radiocarbon/dendrochronological studies. We report ^{14}C age determinations on sequential growth increments from three 'floating' chronologies. A sampling frequency of ~ 10 samples per century was used. Fluctuations in atmospheric ^{14}C levels of 2–3% over several decades can occur, these variations being superimposed on a smoothly changing trend.

THERE is increasing interest and controversy surrounding the issue of calibration of the radiocarbon time scale^{1–5}. The new data and interpretation presented here justify a view of moderation between the opposing extremes of opinion demonstrated by Pearson *et al.*^{1,3} and Suess² respectively.

*Present address: Atlantic Oceanographic Laboratory, Bedford Institute of Oceanography, Dartmouth, Nova Scotia, Canada B2Y 4A2.

We report the first results of a study of past radiocarbon concentrations as reflected in ancient wood. The source of our material was the 'submerged forests' exposed at low tide around the coast of the UK. These submerged forests are the consequence of drowning, by post-glacial sea-level rise, of coastal woodlands. The trees grew at about mean high water mark, usually behind a coastal barrier of some kind, and were usually killed by the rising water table or by the ingress of salt water rather than by catastrophic overwhelming on a large scale. Preliminary radiocarbon measurements (J.A.C. and M.S.B., in preparation) have shown that there is a wide age range of wood available. As rates of isostasy and eustasy are fairly well understood, it is therefore possible, by reference to established sea-level curves⁶, to collect samples for analysis systematically, thus accelerating compilation of a tree-ring chronology. At any one site, there are large numbers of trees, mainly oak with pine and, to a lesser extent, alder, yew and birch. Thus a master chronology can be constructed, this record then being overlapped with chronologies at different locations. The trees are ideal

for dendrochronological studies; individual growth rings are wide and the growth pattern is extremely sensitive and therefore well characterised. (The dendrochronology of the submerged forests is by Heyworth at Aberystwyth.)

The submerged forests also provide excellent material for radiocarbon calibration studies. Trees of different ages all grew at the same altitude, that is, contemporary sea level and should not experience such local effects as higher ambient ^{14}C concentration and *in situ* production which may limit the previously derived bristlecone pine calibration. Plentiful supplies permit collection of large samples and a high sampling frequency, that is, 10 samples per century, with the benefit of duplication of samples and collaborative analyses to maintain the essential high level of objectivity.

Fig. 1 Radiocarbon age (yr BP) versus tree-ring number for a, Borth 4; b, Ynyslas 1; and c, Stolford 4-5 floating chronologies. The vertical error bars indicate the 1σ counting statistics uncertainty associated with individual measurements. On the axis of abscissa age increases to the left, - - - - represents the linear least-squares fit, - - - - represents a least-squares polynomial approximation.

Experimental methods

Ten-year growth increments were separated by hand from the bulk sections which had previously undergone dendrochronological analysis. Individual wood samples were finely chipped in preparation for chemical pretreatment and subsequent conversion to benzene for liquid scintillation counting. Fairhall and Young⁷ have demonstrated that there can be significant differences in the ^{14}C levels of different components of wood, namely cellulose, lignin and resin. Therefore the ^{14}C assay of wood samples was performed on the cellulose fraction only, as the cellulose in each ring is not in dynamic equilibrium with the metabolism of the tree but, once synthesised, remains fixed and thereby satisfies the closed system assumption of the radiocarbon dating method.

Cellulose was extracted by digestion of the finely divided wood in aqueous 2M KOH followed by bleaching in hot $\text{HCl}/\text{NaClO}_2$ for 48 h. The conversion of cellulose to benzene for liquid scintillation counting was performed using standard procedures^{8,9}. Following sample combustion, an aliquot of carbon dioxide was removed for mass spectrometric analysis of

the stable carbon isotope enrichment to allow correction for natural fractionation. Subsequent radiometric measurements were normalised to account for this effect.

The possibility of artificially inducing isotope fractionation through non-quantitative chemical conversion yields was investigated (J.A.C. and M.S.B., in preparation). Aliquots of synthesised benzene were converted to CO_2 and the stable carbon isotope enrichment was measured. Only small differences in the isotopic composition between CO_2 from sample combustion and CO_2 from synthesised benzene were recorded. These differences ($\sim 0.5\%$), uncorrelated with conversion yields, do not contribute significantly to the overall precision.

^{14}C measurement was by liquid scintillation counting on a Packard series 3330 Tricarb spectrometer. Three channels monitored the ^{14}C pulse height spectrum, the positioning of discriminators minimising contributions from ^3H (to $<0.01\%$) and background pulses. The principal channel monitored the ^3H -free portion of the ^{14}C pulse-height spectrum, and the other two channels subdivided the spectrum to monitor small changes in counting efficiency induced by quenching agents. A quench correction calibration was evaluated and all count rates corrected accordingly.

Standard low potassium glass vials were used for ^{14}C counting. A sample volume of 10 ml was adopted and scintillation vials were precoated with matt black paint to this liquid level to reduce spurious cross-talk pulses. Where necessary, samples of synthesised benzene were diluted with spectroscopic grade 'dead' benzene to bring the volume up to the standard amount. The scintillation mixture contained 2 ml of a PPO/POPOP solution and vials were sealed with the supplied, high density, screw-on caps. Close monitoring of spiked samples did not reveal evaporative losses during time periods considerably longer than a typical counting cycle.

The background count rate was determined by repeated measurements on samples of benzene synthesised from materials containing no ^{14}C and samples of spectroscopic grade benzene. A rigorous study of sources of background pulses was conducted. Variability between vials induced by differences in vial weight and by small variations, ± 1 mm, in that part of the vial not masked, was insignificant. In contrast to the work of Pearson *et al.*¹ no correlation with barometric pressure was found. Over several months the variability in background count rate, for a particular vial, expressed as a standard deviation on the mean value of individual counting cycles, was comparable to the uncertainty associated with a single measurement. Hence only statistical variability in the number of counts has a role in background determinations and thus a high degree of long-term instrument stability clearly exists.

Similarly, data on individual NBS oxalic acid samples, compiled over many months, also indicated excellent long-term counter stability, the standard deviation of individual counts about the mean (2.2%) being comparable with the standard deviation of a single measurement (2.4%). Only random variability in the count rates is again found with no long-term evaporative losses. A slow increase in the degree of quenching was found but the sample channels ratio calibration corrected observed count rates. Replicate NBS oxalic acid determinations show a scatter comparable with the uncertainty on an individual count (2-3%). Thus the dominant factor in the precision of our ^{14}C age determination procedure is the counting statistics uncertainty, and errors associated with experimental procedures contribute only a small amount to the overall analytical error.

To ensure the validity of data, several intercalibration studies were carried out. These data will be published elsewhere (J.A.C., M.S.B., L.A. *et al.* in preparation) but agreement between laboratories implies satisfactory analytical accuracy.

Based on the long-term counter stability reflected in the reproducibility of background and modern standard data, and on the findings of the replicate analysis and intercalibration studies, any observed variations in the radiocarbon/tree-ring data presented here can be attributed to true changes in atmos-

pheric ^{14}C concentrations rather than to experimental variability.

Results and discussion

The results of sequential growth-increment analysis of three floating chronologies are presented in Table 1 and Fig. 1. The shortest chronology, spanning 80 yr, was pine wood from the Ynylas exposure (YS-1, $52^{\circ}29'\text{N}$, $4^{\circ}4'\text{W}$), and the two longer oak chronologies from Borth, Cardigan Bay (BH-4, $52^{\circ}29'\text{N}$, $4^{\circ}4'\text{W}$) and Stolford, Bridgewater Bay, Somerset (SD-4-5, $51^{\circ}12'\text{N}$, $3^{\circ}6'\text{W}$) comprised respectively 155 yr and 360 yr. Figure 2 shows results for an additional oak timber recovered from a late prehistoric site in north-east Scotland. Analysis of these samples was shared with the radiocarbon laboratory of the Scottish Universities Research and Reactor Centre, East Kilbride. Sample preparation was performed at East Kilbride with ^{14}C counting being carried out at the Glasgow laboratory. (Details of the floating chronology are published elsewhere¹⁰.) The tree-ring numbering sequence was from the oldest growth ring to the youngest. On each radiocarbon analysis, one sigma counting errors are given based on accumulated sample counts and on established modern standard and background uncertainties. This error also includes a contribution from the imprecision of stable carbon isotope enrichment measurement required for correction for natural fractionation.

Analysis of tree-ring/radiocarbon data for possible variations in the natural ^{14}C content of the atmosphere requires subjectivity in the selection of a relationship between the two time scales and there is therefore little to choose between statistical fitting and free-hand drawing. As relatively short time periods are presented here only a simple least-squares model is considered and non-random variability about this trend line is discussed below.

Linear least-squares analysis was applied to the data. If the linear model is to be a good approximation to the results, then the mean square deviation about the regression line (MSDR)

Growth-ring numbers increase from the old to young extremes of the sequences

Fig. 2 Radiocarbon age (yr BP) versus tree-ring number for Cullykhan 1 floating chronology¹⁰. Vertical error bars indicate 1σ counting statistics uncertainty associated with individual measurements. — — — And — — — represent respectively linear and polynomial approximations to the data.

should reflect only the analytical contribution which, for the Glasgow laboratory, is dominated by the counting statistics uncertainty ($\bar{\epsilon}_c^2$). Table 2 compares the observed MSDR and $\bar{\epsilon}_c^2$ values. In the case of the short pine chronology, YS-1, the linear model is a reasonable fit to the trend line (Fig. 1), indicating that, during the time period represented by this tree-ring section, atmospheric ^{14}C concentrations were decreasing at approximately 0.5% per century parallel to growth. The linear approximation is not good in the case of oak sections BH-4, SD-4-5 and CK-1, the mean square deviation terms considerably exceeding the expected values based solely on analytical uncertainty. The trend lines for these floating sequences indicate that during the BH-4 chronology atmospheric ^{14}C concentration was decreasing at 0.8% per century whereas for the Stolford chronology the trend was one of increasing ^{14}C at 1.5% per century. Over the 250 yr Cullykhan growth period a general decrease of 1.5% per century is evident. Polynomial fitting applied to the three oak chronologies reduces the discrepancy between observed and expected values of MSDR (see Figs 1 and 2). Nevertheless, the fit remains unsatisfactory.

Visual inspection of the tree-ring chronologies indicates non-linear trends in the ^{14}C age profile. For example, the rapid increases in atmospheric ^{14}C displayed at the old and young extremes of the Stolford oak chronology are clearly non-random effects. Fluctuations such as these, amounting to 2-3% in 50 yr, have not generally been observed in previously reported bristlecone pine-radiocarbon data. This may be due to a damping effect arising from the lower sampling frequency of the American work¹¹. Reduction of the sampling frequency to 5 per century, whether as contiguous 20-yr samples or as five discrete samples, seems to smooth the Glasgow data. For example, if the Stolford data are subjected to averaging of adjacent sections to provide five samples of 20 rings per century, the MSDR decreases from 8,455 to 4,797.

Thus, for the time periods measured, the atmospheric ^{14}C concentration seems to have changed smoothly with occasional more rapid fluctuations superimposed on the gradual trends. This evidence is therefore between the traditional views either of a rapidly wriggling or almost linearly changing ^{14}C record. Periods of stability and of rapid fluctuation apparently occur in succession. While these findings apparently contradict, in particular, the results obtained from the Irish bog oak measurements, the real variability in the submerged forest data is believed to be a consequence of the increased sampling frequency used in the latter work. For the same reason, short-term variability of 2-3% over several decades is generally more rapid than those proposed in the bristlecone pine chronology.

A possible explanation for the perturbations may be that ^{14}C in wood, but not necessarily ^{14}C in the atmosphere as integrated over each year, may experience local effects. Lerman *et al.*¹² have reported small differences in the ^{14}C specific activity of tree rings from different locations. Furthermore, the work of Young

Table 2 Comparison of mean square deviation residuals

Floating sequence	Observed residual MSDR	Expected residual ($\bar{\epsilon}^2$)
Borth 4	5,577	2,016
Ynyslas 1	3,424	2,601
Stolford 4-5	8,455	3,448
Cullykhan 1	12,030	1,399

Expected value is based on counting statistics uncertainty, observed value is calculated by linear least-squares analysis of the floating sequences (Cullykhan 1 is also included).

and Fairhall¹³ on the distribution of fallout ^{14}C , has shown the existence of significant seasonal, latitudinal and meridional variations in the input of radiocarbon from the stratosphere, the source of natural ^{14}C , to the troposphere. Thus the temporal relationship between the critical periods of tree-ring growth and maximum tropopause instability is likely to be fundamentally important in the incorporation of local effects. Very rapid growth during this time of maximal stratosphere-troposphere incursion should lead to high sensitivity to short-term fluctuations in cosmic-ray-produced ^{14}C . Thus as both the tree-ring growth and stratospheric input periods are brief and tend to coincide (in spring/summer) the ^{14}C record in wood may not reflect the mean annual ^{14}C level throughout the troposphere, the latter being smoothed by atmospheric mixing. Hence, at locations at which stratospheric influx is extensive, tree rings will tend to record higher amplitude variations in ^{14}C content. Transitions from a smooth to irregular ^{14}C trend could therefore reflect either a change in solar, or, on Earth, global parameters such as geomagnetism, or could simply imply modification of meteorological conditions at the sampling site. The exceptionally slow growth of bristlecone pine wood may then give rise to a much slower response through a longer storage of nutrients. Clearly ^{14}C measurements on single tree rings from the same growth year should show some correlation with ring widths if this is a true source of local effects. Also Tans *et al.*¹⁴ have suggested that differences in ^{14}C in the cellulose fraction of tree rings from the same year but at different locations may reflect a shift in the major growth season of individual trees.

Reiter¹⁵ has shown that influxes of stratospheric air into the troposphere can be triggered by solar flares. As present-day transport of natural ^{14}C cannot be observed directly because of the effect of fallout radiocarbon, evidence must be based on the distribution of those sister cosmogenic radionuclides which were not produced in nuclear weapon tests. Thus measurements of ground-level concentrations of ^7Be and ^{32}P following such events on the Sun have shown increases of 50–100%, which are clearly not related to production rate changes. Moreover the elevated levels of these radionuclides persist for several days. If similar local and short-term enrichments of tropospheric ^{14}C occur during the tree-ring growth period, variability in the ^{14}C record in wood is quite feasible.

The full value of the floating tree-ring sequence data can only be assessed when they become fixed on an absolute scale. Statistical comparison of the submerged forest floating chronologies with a master chronology such as the bristlecone pine tree-ring record, using the method of Clark and Renfrew¹⁶, is unsatisfactory in this case because of the disparate sampling frequency. Comparisons have, however, been made for the UK data. Differences in the growth pattern of submerged forest oak and pine wood sections preclude dendrochronological overlapping of the tree-ring records. Statistical comparison of Ynyslas 1 (pine) to Stolford 4-5 (oak) shows the excellent agreement of the ^{14}C data. In Fig. 1, the tree-ring axes for these chronologies have been aligned to show this concordance. Matching of the Borth 4 (oak) chronology with a section of the Irish bog oak chronology is shown in Fig. 3. The agreement between the two floating chronologies is good. Although for the time period studied both laboratories agree about the overall trend in atmospheric ^{14}C concentrations, the higher sampling frequency of the Glasgow work suggests that there are short-term variations superimposed on this trend.

The manipulation of floating and master chronologies to produce a statistical fit requires linear least-squares analysis of the separate chronologies as well as combined least-squares analysis yielding the placement of the floating series on the master time-scale. With the Irish tree-ring sequence taken as master chronology, analysis of variance indicated that the average uncertainty associated with a Belfast radiocarbon assay, shown by the mean square deviation about the regression, is ~ 35 yr. Such a value is greater than the 25-yr analytical error reported by Pearson *et al.*¹. This ± 25 -yr uncertainty was calculated by combining error contributions assessed by laboratory standardisation (Baillie, personal communication). However, the magnitude of the uncertainty indicated by the regression analysis suggests either that the laboratory standardisation has failed to evaluate all of the uncertainty associated with the ^{14}C assay procedures, or that there is an additional, non-experimental contribution to the total variability.

The statistical fit produced by the treatment of Clark and Renfrew is limited by the precision of the radiocarbon data comprising the floating and master chronologies. Thus, the comparison of Borth 4 with the Irish chronology is limited mainly by the higher average variability of the submerged forest data. The Belfast tree-ring/radiocarbon data have also been aligned against an absolute chronology, presumably the bristlecone pine dendrochronology. This analysis, using an interactive data analysis technique (Baillie, personal communication), places the Belfast data to within 10 yr on the absolute time scale. Bearing in mind the ± 25 yr uncertainty for the floating chronology radiocarbon data and ~ 40 yr for the bristlecone pine ^{14}C analyses, the apparent precision of the fit seems optimistic. Pearson *et al.*¹ predict an ultimate precision for their ^{14}C analyses of ± 12 yr resulting solely from an increase in counting time. At present, quoted counting errors are $< \pm 17$ yr, implying an uncertainty arising from non-counting sources of at least ± 18 yr. Hence it would not be possible to decrease the total uncertainty associated with ^{14}C assay by increasing the counting time.

Fig. 3 Statistical comparison of Borth 4 chronology against a section of the Irish bog oak chronology. ● Represents the Irish data with associated ± 25 yr uncertainty, □ represents the submerged forest data with appropriate 1σ counting error.

In conclusion, ^{14}C measurements on floating chronologies from the UK submerged forests indicate that short-term variations in natural radiocarbon concentrations can occur. Fluctuations of 2–3% over several decades superimposed on smoothly changing trend have been detected with a sampling frequency of ~ 10 samples per century. Periods of relative stability of ^{14}C also seem to occur. Until the past ^{14}C record is precisely defined, therefore, calibration of the radiocarbon timescale must continue to involve a significant uncertainty and the accuracy of existing radiocarbon dating techniques will remain correspondingly limited.

We thank Dr A. Heyworth for bringing this source of wood to our attention and for supplying samples of dendrochronologically dated wood, also T. Aitchison for statistical advice. J.A.C. acknowledges the financial support of the NERC.

Crystal structure and molecular interactions of tropomyosin

G. N. Phillips, Jr, E. E. Lattman*, P. Cummins†, K. Y. Lee & C. Cohen

Rosenstiel Basic Medical Sciences Research Center, Brandeis University, Waltham, Massachusetts 02154

The three-dimensional structure of tropomyosin filaments has been determined by X-ray crystallography. The ends of the molecules were located by reference to the single pair of cysteine residues. Departures from the α -helical-coiled coil conformation may occur in localised domains along the molecule as well as at the overlapping ends.

TROPOMYOSIN is a key protein in the regulation of muscle contraction. The molecule is a two-chain α -helical-coiled coil that forms filaments wound in the two grooves of the actin helix. In many muscles, a calcium-sensitive protein complex, troponin, which binds to both tropomyosin and actin, controls contraction^{1,2}. Tropomyosin is present in all muscles, and most species have two populations with slightly different sequences termed α and β . Tropomyosin from rabbit cardiac muscle contains only the α subunit^{3,4}. The complete sequence of the α -chain of rabbit tropomyosin, comprising 284 residues, has been determined^{5,6}. There is a short-range periodicity of nonpolar residues, as envisaged in Crick's model for the coiled coil⁷ so that a regular pattern of interactions stabilises the structure⁸. The two identical chains in the molecule run in the same sense⁹; and have little or no relative stagger, as the single cysteine residue at position 190 can form an intramolecular disulphide crosslink (refs 10–13 and P.C. and C.C., unpublished observations). Analyses of the tropomyosin sequence^{14–17} have led to a model where the two chains are in exact register and bond through head-to-tail linkages to form filaments. A 14-fold repeat of acidic and nonpolar residues has also been demonstrated and related to muscle regulation^{14,17}.

X-ray diffraction studies of whole muscle have shown that the location of tropomyosin on the actin helix depends on the states of troponin: at low levels of Ca^{2+} , tropomyosin prevents the interaction of nucleotide-containing myosin heads with actin; when contraction is turned 'on', tropomyosin moves deeper into the actin groove, permitting the myosin heads to bind to actin^{18–20}. This work has been extended by three-dimensional reconstruction of thin filaments from electron micrographs²¹. One troponin complex binds to each tropomyosin molecule, probably about one-third of the distance from its C terminus^{22–24}. McLachlan and Stewart¹⁷ have interpreted the 14 quasi-equivalent zones on tropomyosin as two sets of alternative binding sites for actin. When tropomyosin is bound to the actin filament it would make seven half-twists in one molecular length, so that quasi-equivalent regions of the coiled coil would

link to seven identical actin monomers in the 'off' position. When the muscle is switched 'on', the tropomyosin molecule would make a quarter-turn, and the seven quasi-equivalent sites on the molecule would interact with a second set of seven sites on actin. These arguments, necessarily speculative, assume a uniformly α -helical tropomyosin molecule that makes highly regular symmetrical interactions.

Tropomyosin crystals²⁵ have a uniquely high water content of 95% and are made up of an open meshwork of cross-connected filaments. One projection of the crystal has been solved⁹, and shows that the molecules are bonded head-to-tail to form filaments that are bent into gentle sinusoids, implying a supercoiling of the coiled-coil structure. Further studies have shown that the filaments run parallel to the body diagonals of the unit cell with an effective length of a molecule in the filament of 410 ± 4 Å (refs 23, 26). The 385-Å axial repeat of troponin in muscle²⁷ thus indicates that there is a regular bending or 'kinking' of the filaments as they wind in the actin grooves²⁶. Small amounts of troponin can be incorporated into the crystal lattice and produce changes in unit cell parameters and molecular bending; these motions may be related to those occurring in the thin filaments of muscle^{23,26,27}.

We have determined the low-resolution structure of tropomyosin by single crystal X-ray diffraction analysis. The Bragg reflections used in this study extend to 20 Å, near the limit for this crystal form, and from these data, based on a solution derived from the three centric projections of the crystal, the three-dimensional electron density map has been calculated. We describe the winding of the tropomyosin filaments in three dimensions, the precise molecular length, locations of cross connections, molecular motions in the crystal lattice, and a preliminary report on the relationship of the amino acid sequence to the observed structure, including the location and possible conformation of the molecular ends.

Preparation and X-ray photography of tropomyosin

Tropomyosin was prepared as described by P.C. and Perry⁴ from frozen rabbit cardiac muscle. The procedure is based on the method of Bailey²⁵ with the following modifications. Muscle was homogenised with an equal volume of 50 mM KCl, 10 mM Tris-HCl, 0.5 mM EDTA, pH 7.5, and allowed to stand for 30 min. After centrifugation at 1,000g for 15 min, the supernatant was discarded and the residue washed several times more to remove as much blood as possible. Dried muscle fibre was extracted with 1 M KCl, 25 mM Tris-HCl, 1 mM dithiothreitol (DDT) and 0.5 mM EDTA, pH 8.0, and ammonium sulphate fractionation cycles were carried out in 0.2 M KCl, 5 mM Tris-

* Present address: Department of Biophysics, Johns Hopkins University School of Medicine, Baltimore, Maryland 21205.

† Present address: Department of Cardiovascular Medicine, University of Birmingham, Queen Elizabeth Hospital, Birmingham, UK

HCl, 1 mM DTT and 0.5 mM EDTA, pH 7.9. After fractionation, tropomyosin solutions were dialysed exhaustively against 1 mM DTT, and freeze dried.

Tropomyosin crystals were grown in quartz capillary tubes as previously described⁹. The final pH of the crystallising solution was 5.8. To grow mercury-labelled crystals, the cysteines of tropomyosin were reacted with approximately stoichiometric amounts of the organomercurial 2-chloromercuri-4, 6-dinitrophenol²⁸. After dialysis to remove unreacted mercurial the protein was set up to crystallise in the usual way, with the addition of 0.1–1.0 μ M mercurial for stability. Assays for free sulphhydryl groups indicated essentially complete reaction when at least 1.0 Hg per SH group was present initially.

X-ray photographs of crystals in mother liquor were taken at 2–4°C using an air-stream cooling device²⁹. Three-dimensional data were collected by screened precession photography from crystals that had been reacted with 0.6 mercurial per SH group. The unit cell parameters for these crystals were: $a = 120.0 \pm 0.5$ Å; $b = 241.7 \pm 1$ Å; $c = 296.0 \pm 1$ Å. Over 95% of the reflections with Bragg spacings greater than 20 Å were examined. Although the maximum Bragg angle for our data is only about 3°, precession angles up to 21° were required to reduce the radius of the blind region in upper-level photographs to an acceptable value. (Within one film pack R values were typically 0.08.) Least-squares scaling of all film packs produced a data set of 352 reflections with an overall R of 0.077, where

$$R = \frac{\sum_i |I_{\text{ave}} - I_i|}{\sum_i I_i}$$

Space group determination

The space group of Bailey tropomyosin crystals has been difficult to determine because of the lack of strong diffraction along the reciprocal lattice axes. The pmg symmetry of the [100] was unambiguously determined from X-ray patterns in conjunction with electron micrographs of negatively stained crystals (Fig. 1). Moreover, early X-ray photographs showed $h = \text{odd}$ reflections along $h00$ to be absent, so that the symmetry element along a was taken to be a twofold screw axis. The space group was therefore originally reported to be $P2_12_12$ (ref. 9). Because of the nature of the transform, however, the data along $h00$ are generally very weak. A few photographs obtained later showed observable 100 reflections, indicating that the space group was $P22_12$ (refs 23, 26). Of the many crystals recently examined, only one had observable $h = \text{odd}$ reflections.

There are two strong arguments in favour of the space group being $P2_12_12$, despite the occasionally observed weak 100. The first uses the minimum wavelength principle. The large unit cell

and localisation of the protein within 5% of the cell volume produce a reciprocal lattice sampling that is fine relative to the molecular transform, especially at very low resolution. This means that along reciprocal lattice lines perpendicular to the filament paths there can be no abrupt intensity changes except those caused by space group extinctions. The 210 and 201 reflections are always very strong whereas the 100 reflection is always either absent or weak (Fig. 2). The difference in intensity between the 100 and its neighbouring reflections is too great to be caused by changes in the molecular transform, and there must therefore be an extinction arising from the symmetry of the structure. Second, in a case where a weak 100 reflection was observed, inspection by polarised light revealed within the crystal a small crystal of a different orientation. We would attribute atypical photographs to anomalies in crystal growth. In all subsequent discussions, therefore, the space group is taken to be $P2_12_12$.

In the case of tropomyosin, the existence of screw axes instead of diads parallel to the a axis has implications about the contacts that can be made between filaments. There can be no contact in regions near the screw axes, because the filaments, which have a maximum diameter of 25 Å, are separated by one-half the unit cell, or 60 Å. This means that the bonding regions are confined to a relatively limited area of the molecule (see below).

Solution of the structure

The approximate path of the molecule in three dimensions can be deduced from the intensity distributions in the three centric projections. In special cases it is possible to solve a structure from these projections; the continuity of the tropomyosin filaments and the large solvent content make this one such a case. The projections, in fact, contain some redundancy: two projections are sufficient to determine x , y and z ; the third provides an independent check.

A net of strands has been visualised in the electron microscope and established as the view down the a axis of the crystal (Fig. 1). The X-ray pattern could then be interpreted as arising from a pair of gently curved filaments running along the cell diagonals⁹. The cross connections between filaments produce a kite-shaped mesh for the net, so that the filaments have a long and a short arm. Note that all three views show similar intensity distributions, despite the change in scaling due to differences in lattice spacings (Fig. 2). As in the [100] projection, these patterns are indicative of sinusoids with small separations of filaments in projection. Hence, the problem of determining the three-dimensional filament path becomes one of correlating the origins of the projections. Because of the fine reciprocal lattice sampling, preliminary electron density maps can be calculated for each of the projections in a straightforward manner. For the [010] and [001] projections only three phases are required to calculate maps incorporating the ~ 12 strong reflections in each projection. The phases along the reciprocal space direction perpendicular to the filament will be positive (relative to some origin) and the phases of reflections on rows next to the diagonal will be positive on one side of the diagonal and negative on the other, the two possible choices being related by origin shifts. One has only to choose origins for the projections that produce a three-dimensional filament path consistent with the space group and the continuity of the filament. Only one solution (and its enantiomorph) satisfies these criteria. This approximate filament path was used to model the structure as discussed below.

Refinement

Tropomyosin, with its high solvent content, offers a unique method of correcting initial X-ray diffraction phases, and hence, improving the quality of the electron density map. Phases were first calculated from the Fourier transform of point scatterers placed at small enough intervals along the filament to approximate a uniform rod at 20 Å resolution. About 95% of the unit cell is solvent which must, at this resolution, have a uniform electron density, placing a powerful constraint on the phases.

Fig. 1 Electron micrograph of a tropomyosin crystal corresponding to the view in the [100] direction. The strands form a kite-shaped net with long and short 'arms' defined by cross connections. The insert shows the pairs of tropomyosin filaments making up the strands. Negatively stained with 1% uranyl acetate ($\times 190,000$).

Fig. 2 Precession photographs ($\mu = 3\frac{1}{2}^\circ$) of the three principal projections of tropomyosin taken on a 10-cm camera with a double mirror focusing monochromator. Except for the lattice spacings, note the similarities of all three views. Each projection shows strong spikes arising from closely spaced pairs of filaments. *a*, [100]; *b*, [010]; *c*, [001]. In the [100] projection, nodes arising from the separation of the filaments and their curvature can be seen.

This information was included by seven cycles of setting the solvent region to a constant and calculating a Fourier transform to obtain new phases for an improved electron density map (G.N.P., in preparation). (The final *R* factor between the observed and calculated structure factors was 0.16 compared with 0.35 for the initial model.) Several views of the refined electron density map are given. Figure 3 shows the three-dimensional arrangement of filaments and their cross-connecting regions. Figure 4 shows a single filament sectioned parallel to its axis. It is relatively easy to trace the filament path through the unit cell including the area of cross connections.

Molecular length and three-dimensional winding

The tropomyosin filament winds along a line parallel to the body diagonal of the unit cell. The effective length of the molecule, that is, the repeat along the filament, can be determined to the limit of accuracy of the unit cell parameters. This length was previously estimated from projections as 410 ± 4 Å. As the path can now be traced in three dimensions, we can establish this length more precisely as 410.3 ± 1.4 Å. This information can be used to deduce the number of residues involved in the end-to-end bonding region. Assuming an average axial translation of 1.49 Å per amino acid residue in the α -helix of a perfect coiled coil, the molecular overlap is predicted to be $284 - 410.3/1.49 = 8.6 \pm 1.0$ residues. The three-dimensional winding of the filament is not, in fact, helical, but has the form of an ellipse when projected down the axis of the molecule. The sense of this supercoiling cannot yet be established. The tropomyosin filament is wound in the grooves of the actin helix, with a right-handed sense; and, for illustrative purposes we have chosen right-handed supercoiling of the filaments in the crystal.

Location of the Cys 190 residue

Rabbit cardiac tropomyosin consists of two identical chains of known sequence; there is one cysteine per chain^{5,6}. These SH groups have now been located within the unit cell. X-ray diffraction data to 20 Å have been collected from both Hg-labelled and reduced forms of tropomyosin for two projections, corresponding to views down the [100] and [001] axes. Difference Fourier maps were calculated using the phases obtained by the model building and refinement procedures. A single site is observed in each projection (Fig. 5). (Previous problems with difference Fourier maps of Hg derivatives have been accounted for by the presence of small amounts of

contaminating proteins within the lattice.) The redundancy of measurement of the value of y provides a check on the solution; the values obtained for y agree to within 6 Å. Difference Patterson maps were also calculated to test the validity of the solution. Major peaks were found corresponding to heavy atom positions, although other strong peaks were also present. Efforts are underway to determine the usefulness of including isomorphous replacement data in the structure analysis. The fact that there is a single peak for the two SH groups of the molecule supports a structure where the two chains are in register, although the resolution of the difference Fourier maps does not rule out a small stagger ($< \sim 10$ Å) (see below).

The Hg serves as a marker for the location of Cys 190 along the filament, but leaves a twofold ambiguity, however, in the direction of the polypeptide chain in the filament. If the N to C direction is chosen, as shown in Fig. 4, the intermolecular overlap would occur in the short arm of the filament near a crossover region. The map shows a relatively dense peak at precisely that point. This feature presumably corresponds to the end-to-end molecular overlap. The alternative choice of direction for the polypeptide chain would place the molecular overlap

Fig. 3 The three-dimensional electron density map of tropomyosin. Several unit cells are shown at a slight angle to the [100] direction to illustrate the packing of filaments in the lattice and the location of a single molecule in the structure. (The head and tail of the arrow represent the C and N termini, respectively.) Contour values are at equal increments, the lowest of which is about 0.34 electrons Å⁻³.

Fig. 4 A filament sectioned along its length. The top and bottom view are rotated by 90° about the filament axis. Contour values are the same as in Fig. 3 and sections are at intervals of $4 \text{ \AA}$. Slightly more than one effective molecular repeat is displayed. The arrow shows the direction of the polypeptide chain and the location of the molecular ends.

within a crossover region and does not readily account for the electron-dense region in the short arm. Sequence information can also be used to distinguish these possibilities. A line projection of the electron density was calculated by integrating cross sections of the filament in regions where no crossovers were present. The corresponding 'theoretical' distribution was estimated based on the amino acid sequence and a 9-residue overlap. Relative weights for each amino acid were derived from Hulmes *et al.*³⁰, with the exception of cysteine, which was corrected to include its labelling with Hg. Figure 6 shows the theoretical and observed density profiles for both chain directions. The better fit of the two curves is clearly represented by Fig. 6a and confirms the solution shown in Figs 3 and 4. Introducing a stagger of seven residues did not produce a significant effect, and hence cannot be ruled out. The Hg labelling of β -tropomyosin (which contains an additional pair of SH groups) or a molecule containing an α and a β chain should allow us to confirm this solution of the chain direction.

Molecular structure

We can interpret certain additional features observed in the electron density map on the assumption that the preceding analysis gives the correct direction of the polypeptide chain. We should note initially that one might expect to establish certain parameters of the coiled coil at this resolution. The theoretical molecular cross section is, however, approximately $20 \times 15 \text{ \AA}$. This small difference is not discernible in the structure that we have so far achieved, and we have not, therefore, been able to determine the pitch of the coiled coil, its sense of twist or its phase in the unit cell. (As α -helices are right-handed and the coiled coil is left-handed, when we are able to visualise the twist,

Fig. 5 Difference Fourier projections (dark lines) superimposed on the electron density map (light lines) showing the location of the Hg and, hence, Cys 190. a, [100] projection; b, [001] projection. The difference maps are contoured at values corresponding to the range 2σ – 4σ , where σ is the r.m.s. deviation in the map.

the absolute hand of the supercoiling can be determined.) By comparing the limited intensity data to $15 \text{ \AA}$ with calculated molecular transforms it may soon be possible to visualise these features.

Inspection of the map shows that the run of the filament seems quite continuous (Fig. 4), including the dense region that we have identified as the molecular ends, where a head-to-tail overlap of about nine residues must take place. Here the filament shows only a slight swelling in all directions. If the molecular ends were simple α -helical-coiled coils linked by overlapping of the 'broad faces' (ref. 17), we would expect to see a discontinuity in this region of the map corresponding to a lateral stagger. However, an alternative explanation of this feature is that the molecule might not maintain the α -helical conformation at the ends so that the chains would be joined by intermeshing to form a small globular domain. This kind of link is consistent with both the electron density map and chemical characteristics of the molecule. Predictions of secondary structure based on the amino acid sequence indicate, in fact, that the ends of the chain may not be α -helical; this is particularly true for the sequence at the C terminus, whereas the N terminus does not allow a strong prediction (Argos, personal communication). Tropomyosin has been seen as the archetype of α -helical-coiled coil, but its functional design to form filaments by end-to-end bonding may have produced a specialised structure for the molecular ends.

The general smoothness of curvature of the molecular filaments—apart from the ends—implies that there are no major deviations from coiled coil structures at 4°C . However, this observation does not mean that there are no local regions of 'flexibility'. The filament seems to be slightly kinked in several places in the map. These deviations from a uniform structure may be more pronounced at physiological temperatures.

The molecular filaments can be traced relatively easily through the cross-connecting 'knots' in the lattice. There are two regions of the molecule where intermolecular contacts are made; one is near the C terminus, and the other is about $140 \text{ \AA}$ from the N terminus (Fig. 4). (These 'sticky' regions on the molecule may also be used for cross connections in other polymorphic forms of tropomyosin²³.) Although we can now identify some of the residues involved in the intermolecular bonding, we wish to establish the direction of the molecule in the filament unambiguously (by the use of β -tropomyosin) before reporting the detailed relationship between the amino acid sequence and the electron density map.

Molecular dynamics

The tropomyosin crystal is unique not only because of its high water content but because it is made up of filaments rather than discrete molecules. Moreover, there is only limited contact between filaments in the lattice. Correspondingly, these crystals display some unusual structural features. There are considerable variations in the b and c parameters of the unit cell that have been shown to be related to the presence of other proteins in the lattice²³. We have confirmed and extended these findings. Despite these unit cell differences, however, the length of the body diagonal remains $402 \text{ \AA}$. This figure is the projected molecular repeat along the tropomyosin filament, and its constancy implies that the molecular structure and precise end-to-end overlap are maintained despite small variations in molecular bending that occur in unit cells of different sizes.

A striking aspect of the diffraction patterns is the intense diffuse scattering seen in unscreened photographs. This is due to various types of disorder in the crystal (see ref. 31). The most plausible explanation is that this feature arises from vibrations of the filaments in the crystal lattice. In three dimensions, the diffuse scatter consists of 'disks' normal to the direction of the long arms; there is also a weaker streak associated with the short arm of the filament. This finding implies that the conformation of the long arm of the filament is relatively variable, but that there is also some vibration in the short arm (Fig. 4). This

interpretation is consistent with the following experiments. X-ray photographs have been taken of crystals at 30 °C rather than 4 °C. In these conditions, reflections arising from the long arms but not those from the short arms are essentially eliminated. Moreover, this effect is reversible. This result confirms the difference in stability of the two arms of the filament, and shows that the magnitude of the effect is considerable at physiological temperatures.

Fig. 6 Comparison of the observed (solid lines) and calculated (broken lines) electron density profiles of the tropomyosin filament for the two possible directions of the polypeptide chain. The observed electron density is taken as zero where cross-connecting filaments prevent integration of the molecular cross section. The calculated profiles were obtained by assigning weights to each amino acid in the sequence and convoluting with a gaussian of width appropriate to match the resolution of the observed curve. Curves in *a* correspond more closely than curves in *b* and the chain direction has, therefore, been taken as in *a*.

Relevance to muscle

Our results provide insight into the role of tropomyosin in muscle regulation. The molecular length we have established allows an estimate of the filament's radius of bending when it is bound on the actin helix. Taking the projected axial repeat of tropomyosin as 385 Å, this average radius can be calculated to be 45.2 Å ($(410.3^2 - 385^2)^{1/2} / \pi$). Assuming the same sense of twist, the radius of supercoiling of the molecular filament in the crystal lattice is about one quarter as large as that of tropomyosin on the actin helix. Interactions with actin, therefore, play an important part in determining the precise conformation(s) of tropomyosin in muscle. There must be some local flexibility of the tropomyosin structure to accommodate this large difference in radius of bending. The slight irregularities of the filament seen in the electron density map and the motions of the filament deduced from the diffuse scattering analysis imply localised flexible regions of the molecule³²⁻³⁴ and also indicate that there may be regions of the molecule other than the ends that are not in stable α -helical conformations.

The motions of tropomyosin during regulation depend on the precise structure(s) of the molecule and its specific interactions with actin. Attempts to determine the design of tropomyosin

have led to the recognition of some rather subtle structural features. The sequence results are consistent with an almost fully α -helical-coiled coil molecule; however, certain small regions may depart from this conformation, either in a conserved fashion (at the molecular ends) or only transiently, depending on varying interactions. The effective length of tropomyosin spans seven identical monomers on the thin filament, but there is no sevenfold repeat in the sequence; rather, 14 quasi-equivalent regions have been detected, which differ, however, rather markedly. (A single region of the molecule, for example, binds troponin.)

The presence of the high proportion of α -helical-coiled coil, and the quasi-equivalent bonding regions have led to models for tropomyosin that tend to stress its regular symmetrical features. This is, perhaps, a deceptively simple view. The kind of picture that is now beginning to emerge from our crystallographic analysis, and other studies, is that of a somewhat less regular and rigid structure. In its regulatory role in muscle, the tropomyosin supercoil moves on the actin helix. The molecular motions displayed by tropomyosin supercoils in the crystal lattice may reflect to some extent the real nature of the dynamic elements in the structure (see refs 23, 26). It is likely that at some stage of the contractile cycle, the tropomyosin molecule may be rather loosely wound about the actin helix, perhaps held strongly at only a few sites, and locally kinked at other regions. In view of the unusual characteristics of the molecule that have been deduced thus far, we suggest that the motions of tropomyosin in muscle depend on two aspects of its design: the regular coiled coil structure and quasi-equivalent regions that interact with actin; and the aperiodic features. These uncommon domains may play a critical part in the function of this highly specialised molecule.

Endogenous mammary tumour virus DNA varies among wild mice and segregates during inbreeding

J. Craig Cohen* & Harold E. Varmus

Department of Microbiology, University of California, San Francisco, San Francisco, California, 94143

Proviruses of the mouse mammary tumour virus (MMTV) endogenous to normal mice can be identified by molecular hybridisation and distinguished using restriction endonucleases. Feral mice display marked heterogeneity with respect to the number of copies and the sites of insertion of endogenous MMTV-specific DNA, with occasional mice apparently free of MMTV DNA. Several different MMTV proviruses present in laboratory mice have segregated like stable, independent genetic elements during the inbreeding which followed a cross between Bagg albino and DBA mice 60 years ago. The results favour the hypothesis that endogenous proviruses have been established by multiple, independent infections of germ cells rather than by somatic mutation of ancestral proviruses or of cellular genes.

DNA related to the genomes of retroviruses and capable of directing synthesis of viral gene products has been found endogenous to many animal species^{1,2}, but the origin and function of endogenous proviruses remain relatively obscure. Since retroviruses are extremely widespread in nature and have a very similar genetic organisation in different hosts, they are likely to have a common origin. It has generally been argued that endogenous proviruses have evolved either by alteration of cellular genes⁴ or by rare infection of the germ line(s) of early vertebrates⁵. To account for the retention of functional proviral DNA during speciation, it is attractive to propose that virus-specific DNA serves a function which confers some selective advantage to the host. It is also possible, however, that contemporary retroviruses evolved as viruses from a single progenitor virus and that endogenous proviruses were occasionally established by infection of the germ lines of individuals from diverse species. This proposal does not imply that endogenous proviruses have any utility for the host; their wide distribution might be simply a consequence of the ability of retroviruses to infect germinal cells, thereby introducing stably inherited proviral DNA.

Several features of the mouse mammary tumour virus (MMTV) make it suitable for investigating some of these issues. Pathogenic strains of the virus are transmitted in laboratory mice either as infectious agents in the milk of certain animals or as endogenous proviruses integrated into germ line DNA (refs 6, 7). Molecular hybridisation tests indicate that laboratory and feral mice may harbour approximately 3–15 copies of MMTV DNA per diploid genome^{9–12}; MMTV DNA has also been detected in Asian mice⁹, but little if any viral DNA has been found in rodents outside the genus *Mus*¹³.

Endogenous MMTV DNA differs markedly among feral mice

To characterise virus-specific DNA endogenous to normal cells, most investigators have relied on assays which measure the rate

of formation and stability of hybrids between labelled viral nucleic acids and cellular DNA, often using cellular DNA pooled from several individuals. Restriction endonucleases which recognise sequences within and adjacent to virus-specific DNA allow important refinements in the analysis of viral DNA: fragments generated from internal regions can be used to differentiate closely-related proviruses, and fragments which include adjacent host DNA can be used to identify the location of the proviruses in host DNA¹⁴. Since the recognition sites for these enzymes are short sequences (4–6 base pairs in length), they are likely to be conserved among members of a single species; the single copy DNA of individual mice, for example, appears to manifest less than 1% overall difference in base sequence¹⁵. We have used restriction endonucleases to compare endogenous viral DNA among individual animals, as a means of determining the origin of the DNA. If, for example, MMTV DNA had evolved from element(s) present in a progenitor of *Mus musculus* at a rate similar to that of other non-reiterated DNA, individual mice would be expected to appear similar when analysed for restriction fragments bearing virus-specific sequences.

To perform such tests, we prepared DNA from the livers of 12 wild mice trapped in four geographically distinct areas in California. (The liver is relatively resistant to horizontal infection by MMTV. Using tests for new proviruses in tissues of susceptible animals receiving virus in milk, no new viral DNA could be measured in livers in conditions adequate to detect infection of 1% of the cells¹⁶. Hence we have assumed here that proviruses in hepatic DNA represent only genetically transmitted DNA.) Following digestion with the restriction endonucleases *Pst*I and *Eco*RI, the DNA samples were assayed for fragments containing virus-specific sequences using agarose gel electrophoresis and the DNA transfer method¹⁷. These two enzymes were chosen because mapping studies with both viral DNA introduced into cells by acute infection¹⁸ and virus-specific DNA endogenous to inbred mice (see below; also ref. 16 and our unpublished results) indicated that *Pst*I recognises several sites within proviral DNA, whereas *Eco*RI cleaves at a single site (Fig. 1). Hence *Pst*I would be expected to generate several virus-specific fragments whose size would depend solely on sites within viral DNA, while cleavage of each provirus with *Eco*RI would normally produce two fragments whose size depends on sites in flanking cellular DNA. This approach has been used to show that MMTV proviruses introduced by experimental infection are located at many sites in cellular DNA (as manifested by variations in the size of *Eco*RI fragments), but that the same small region of viral DNA is always joined to cellular DNA^{16,19} (see legend to Fig. 1).

Analysis of the *Pst*I digests of wild mouse DNA (Fig. 2) showed all of the tested mice to be unique with respect to their MMTV proviruses, although fragments of certain sizes (for example, molecular weights of 3.3, 3.1, 2.5, 1.1, 0.9, 0.6, and 0.5×10^6) could be found in several of the digests. It is presumably significant that these fragments are observed in digests of DNA from inbred strains (Fig. 1; also Fig. 4, Table 1); we infer that units of viral DNA with very similar or identical internal sequences are variably distributed throughout the feral (and inbred) mouse population. We noted with particular interest the

* Present address: Department of Microbiology and Immunology, Tulane University School of Medicine, New Orleans, Louisiana, 70112.

widespread occurrence (Fig. 2, lanes D, E, F, G, J, L, and M) of the constellation of *Pst*I fragments of 2.5, 1.1, 0.9 and 0.6×10^6 Mr also associated with the provirus acquired by infection with MMTV commonly isolated from milk (Fig. 1); in at least one case (lane F), these fragments appear to be present in the absence of any others.

The most striking finding, however, was the virtual absence of MMTV-related DNA in two of the 12 specimens examined with *Pst*I (Fig. 2, lanes H and I); annealing with a labelled MMTV-specific DNA revealed only a faint band, corresponding to a fragment of 9.0×10^6 MW common to all DNAs. Annealing of DNA immobilised on the same filter with labelled cDNA specific for rRNA demonstrated fragments common to all digests, including those in lanes H and I (bottom panel, Fig. 2), thereby excluding the possibility that the poverty of MMTV-specific bands in lanes H and I was due to some mechanical impediment to annealing. Moreover, several additional wild mice from the same location (Lake Casitas, California) have been found free of MMTV DNA (unpublished results of J.C.C. and M. Gardner). The common 9.0×10^6 MW fragment in annealings with both MMTV- and rRNA-specific cDNAs indicates a minor contamination of our viral cDNA with ribosomal sequences.

Examination of MMTV proviral DNA in feral mice with *Eco*RI produced grossly heterogeneous patterns (Fig. 3). Again, all tested mice were different; but in the *Eco*RI digests few, if any, fragments were common to two or more individuals, and the fragment sizes were not identical to those encountered in digests of DNA from inbred mice (see below, Fig. 5). One sample found to be free of MMTV-specific *Pst*I fragments (Fig. 2, lane I) also proved to lack *Eco*RI fragments which react with MMTV-specific cDNA (Fig. 3, lane I). The other negative

Fig. 1 Restriction endonuclease maps of MMTV DNA. The sites of cleavage of MMTV DNA and adjacent cellular DNA by the two enzymes used in this report are indicated by arrows (pointing down for *Eco*RI sites, up for *Pst*I sites). The numbers denote the molecular weights $\times 10^{-6}$ of consequent fragments. *a*, Linear form of unintegrated MMTV DNA in cultured cells infected by milk-borne virus from mouse strains GR or C₃H (refs 16 and 18). The linear form is approximately colinear with a subunit of viral RNA, with the right-hand half of viral DNA representing the 3' half of viral RNA¹⁸. Integrated MMTV DNA in cells infected by these viruses is colinear with the unintegrated linear species and has been found inserted in many different positions in host genomes^{16,19}. (We have not attempted to illustrate the many possible restriction endonuclease sites in cellular DNA adjacent to viral DNA introduced by experimental infection.) *b*, *c*, and *d*, Units of MMTV DNA found endogenous to certain inbred mice of the Bagg albino $\times$ DBA lineage (Fig. 6, Tables 1 and 2). The maps for Unit II (*b*) and Unit III (*c*) were determined by secondary cleavages of isolated *Eco*RI fragments of BALB/c mouse DNA; details will be presented elsewhere (unpublished data of J.C.C., J. Majors, and H.E.V.). The *Pst*I fragments of 1.2 (Unit II), and 0.2 and 3.4×10^6 Mr (Unit III) could be visualised well only after annealing with cDNA specific for the 3' terminus of viral RNA and were not therefore used routinely to identify these proviruses. (cDNAs specific for either end of viral RNA anneal to both ends of viral DNA^{18,19}, indicating that terminally redundant sequences are present in MMTV DNA in a manner similar to that described for avian sarcoma virus DNA³⁷⁻⁴⁰.) The *Pst*I map of Unit IV of endogenous MMTV DNA (*d*) is identical to the *Pst*I map of proviruses acquired by infection with milk-borne viruses (*a*). The question marks indicate uncertainty about the assignment of *Eco*RI sites in flanking cellular DNA to the right or left side of the provirus.

Fig. 2 Products of *Pst*I digestion of MMTV DNA endogenous to feral mice. DNA was extracted from the livers of individual wild mice using established procedures^{9,16}. Samples of 10 μ g were digested to completion with *Pst*I (prepared as described by Greene *et al.*⁴¹) and subjected to electrophoresis (1–2 V cm^{-1}) in horizontal 3–6 mm slab gels of 0.8% agarose (Seakem) in buffer containing 0.04 M Tris-acetate, pH 8.15, 0.02 M Na acetate, 0.018 M NaCl, 0.002 M Na₂EDTA. After staining with 5 $\mu\text{g ml}^{-1}$ ethidium bromide and subsequent inspection under UV illumination, the DNA was transferred to sheets of nitrocellulose (Schleicher and Schull) using the procedure of Southern¹⁷ as previously described^{16,18}. Filters were baked *in vacuo* for 2 h at 80 °C, incubated at 41 °C in a pre-annealing mixture containing 50% formamide, Denhardt's solution⁴², 20 $\mu\text{g ml}^{-1}$ alkali sheared and denatured salmon sperm DNA, 0.05 M HEPES buffer, pH 7.0, and $3 \times \text{SSC}$ ($\text{SSC} = 0.15 \text{ M NaCl}$, 0.015 M Na citrate), then incubated 60–72 h at 41 °C in a minimal volume of a similar mixture initially containing $1-2 \times 10^6$ c.p.m. ml^{-1} of MMTV ³²P-cDNA (upper panel). Following the washing and autographic procedures (see below), the filter subsequently was incubated with $1-2 \times 10^6$ c.p.m. ml^{-1} ribosomal ³²P-cDNA (lower panel) first at 68 °C for 1 h to denature hybrids with MMTV-specific cDNA and then at 41 °C for 60–72 h. These cDNAs were prepared as described by Shank *et al.*¹⁸ using oligomers of calf thymus DNA to prime synthesis randomly on either MMTV 20–35S RNA or 18S and 28S rRNA²⁷. After incubation with specific cDNAs the filters were rinsed briefly at 23 °C with $2 \times \text{SSC}$, incubated at 50 °C for 1–2 h with two changes of $0.1 \times \text{SSC}$, 0.1% SDS, and washed frequently at 23 °C with $0.1 \times \text{SSC}$. Kodak Royal X-omat film was exposed to the filter using Cronex 'Lightning Plus' intensifying screens (Dupont) for up to 10 d at -70°C ⁴³. *Hind*III fragments of ³²P-DNA were included as MW standards (not shown). The MW $\times 10^{-6}$ of major viral-specific fragments are shown on the left for lanes A–G and on the right for H–M. *Pst*I fragments of MMTV DNA endogenous to BALB/c mice, lanes A and M, and from Californian wild mice⁴⁴ obtained from Bouquet Canyon, lanes B, C, and D; San Francisco, lanes E, F, and G; Lake Casitas, lanes H, I, and J, and Norwalk, lanes K, L, and M.

sample was not tested with *Eco*RI. Although the MMTV proviruses in feral mice have internal similarities, as judged by the shared, relatively small *Pst*I fragments (Fig. 2), they are presumably located at different positions in cellular DNA, as judged by the variability of the size of the *Eco*RI fragments (Fig. 3). (The large sizes of these fragments supports our prediction that at least one of the determining sites is in flanking host DNA.) The results are most readily interpreted as evidence for variable numbers of independent integrations of MMTV proviruses at various sites in host DNA. The situation appears analogous to that in MMTV-infected tissues and cells, with viral DNA inserted at different sites in host DNA in each independently infected cell^{16,19}.

We have considered the possibility that some of our results could reflect a high degree of mutability of DNA surrounding endogenous proviral DNA, with relative conservation of the internal regions (as reflected in results of digestion with *Pst*I (Fig. 2) and by previous thermal denaturation studies⁹). However, this interpretation cannot account for the absence of proviral

Fig. 3 Products of *EcoRI* digestion of MMTV DNA endogenous to feral mice. DNAs from the feral mice analysed in the experiment shown in Fig. 2 were digested with *EcoRI* (a gift from P. Greene) and analysed as described in the legend to Fig. 2. *HindIII* fragments (lane A) and *EcoRI* fragments (lane O) of phage λ ^{32} P-DNA served as MW standards for lanes B-H and I-N, respectively. *EcoRI* fragments of MMTV proviral DNA from BALB/c mice, lanes B and N; Bouquet Canyon, lanes C, D, and E (lanes B, C, and D, respectively in Fig. 1); San Francisco, lanes F, G, and H (lanes E, F, and G, respectively in Fig. 1); Lake Casitas, lanes I and J (lanes I and J, respectively in Fig. 1); and Norwalk, lanes K, L, and M (lanes K, L and M, respectively in Fig. 2).

DNA in some wild mice or for what seem to be major differences in the number of units of viral DNA among the wild mice (for example, compare the numbers of virus-specific *EcoRI* fragments in lanes F, H, J, and M with those in lanes C, E, G, and K in Fig. 3). In addition, the required frequency of change in the hexanucleotide recognition sequences for *EcoRI* in *Mus musculus* DNA would greatly exceed the base sequence divergence expected among individuals within a single species of *Mus*^{15,20}.

Units of endogenous MMTV DNA segregate like stable genetic elements during inbreeding

Our results could also be seen as evidence of a marked propensity of retroviral DNA to undergo genetic gymnastics, including deletion, translocation, rearrangement, and amplification, in manner similar to certain elements in bacteria²¹ or predicted for retroviral DNA in the provirus hypothesis⁴. (The latter hypothesis cannot, by itself, account for the absence of viral DNA from wild mice, but we consider the possibility that it might be operative in conjunction with other mechanisms for radical genetic change.) We have been able to perform a provisional test of this explanation by examining whether multiple units of endogenous MMTV DNA have segregated like stable genetic elements, retaining their characteristic restriction endonuclease recognition sites, during the almost 60 yr of inbreeding which followed the mating of a Bagg albino female with a DBA male in 1920 (ref. 22).

Figures 4 and 5 illustrate the patterns of virus-specific fragments in *PstI* and *EcoRI* digests of DNA obtained from the livers of mice from several contemporary colonies descended from the progeny of the initial Bagg albino $\times$ DNA mating. Despite several obvious differences among these digests (to be considered below), the similarities are very striking, especially when they are viewed in comparison with the digests of DNA from feral mice (Figs 2 and 3). As the tested mice were obtained from branches of the genealogical tree that had been separated for nearly 60 yr (see Fig. 6, ref. 22), the apparent stability of restriction sites suggested that neither viral DNA nor flanking cellular DNA was highly mutable and that the elements of endogenous DNA might be amenable to segregation analysis.

To simplify this analysis, we correlated the presence of *EcoRI* and *PstI* fragments in digests of each sample, as summarised in Table 1. In making these correlations we took advantage of mapping data from related studies. (1) We knew from studies of cells and tissues infected by milk-borne MMTV¹⁶ that *PstI* fragments of 2.5 and 0.6×10^6 MW could be used to distinguish provirus acquired by horizontal infection from proviruses found endogenous to certain inbred mice (for example BALB/c). As shown here, several other strains derived from the Bagg albino $\times$ DBA mating (C₃H/Bi, CBA/J, and CBA/St; Fig. 4) carry a provirus indistinguishable with this enzyme from the provirus acquired by infection with milk-borne MMTV (Fig. 1a, d). This provirus (Unit IV in Table 1) is also associated in these mice with the appearance of *EcoRI* fragments of 7.0 and 6.0×10^6 MW; Unit IV can be found in contemporary DBA/2 mice and presumably was carried by the DBA male participating in the original cross. (2) We have generated physical maps of the MMTV DNA endogenous to contemporary BALB/c (Fig. 1b, c; Table 1) by performing secondary digestions with several endonucleases of isolated *EcoRI* fragments of BALB/c liver DNA bearing viral sequences (data not shown). These studies validated several of the associations we were able to make on genetic grounds between *PstI* and *EcoRI* fragments, and they revealed the structure of three units of endogenous viral DNA (I-III) which differ from the provirus (Unit IV) resembling DNA acquired by infection with milk-borne MMTV. These three units include two (Units II and III) very similar in complexity and organisation to the proviruses acquired by infection with milk-borne virus (that is 5×10^6 – 6×10^6 Mr); the third (Unit I) bears viral sequences with about one-half the complexity of a unit length provirus (Table 1).

These approaches led to the definition of six units of endogenous MMTV DNA which seem to be segregating in the progeny of Bagg albino $\times$ DBA; the restriction fragments associated with each unit are listed in Table 1 to facilitate inspection of the digests shown in Figs 4 and 5. When each of the contemporary colonies was scored for carriage of each of the six units, we were able to define six genotypes (A-F, Table 2). No strain carried less than two units of endogenous DNA, but only one unit (Unit II) was present in the DNA of all the laboratory mice

Fig. 4 Products of *PstI* digestion of MMTV DNA endogenous to progeny of Bagg albino $\times$ DBA. 10 μ g of DNA from the livers of individual mice from the strains indicated were analysed as described in Fig. 2. *HindIII* fragments of λ DNA were used as MW markers and the MW $\times 10^{-6}$ of major MMTV-specific fragments are indicated to the left of each gel. Lane A, C₃H/Bi; B, C₃H/St; C, CBA/J; D, CBA/CaJ; E, CBA/Ht-6; F, C₃H/HeN; G, C₃H/HeJ; H, CBA/N; I, C₃H/Bi; J, C₃H/An; K, BALB/c; L, DBA/2; M, CBA/St.

Table 1 Restriction fragments derived from six defined units of endogenous MMTV DNA

Units of endogenous MMTV DNA	<i>Pst</i> I fragments	<i>Eco</i> RI fragments
I	0.9*	10.0
II	3.3, 1.1, 0.5	5.0, 4.0
III	3.1†, 1.1, 0.5	6.0, 4.7
IV	4.5, 2.5, 1.1, 0.9, 0.6	7.0, 6.0‡
V§	3.1†	3.9¶, 3.5, 2.7
VI§	—	5.4, 9.0, 1.0**

The *Pst*I and *Eco*RI fragments useful for the identification of each of the six units of endogenous MMTV DNA observed in the progeny of Bagg albino × DBA are listed according to molecular weight ($MW \times 10^{-6}$). For discussion of the definition of the units, see text. The restriction endonuclease maps of Units II, III, and IV are illustrated in Fig. 1.

* The 0.9 *Pst*I fragment is diagnostic of Unit I when it appears in the absence of Unit IV.

† *Pst*I fragments of 3.1 are derived from Units III and V, but the corresponding band is equal in intensity to the 3.3 *Pst*I band in the first case, but is less intense in the second (compare lanes G and H in Fig. 4).

‡ Two *Eco*RI fragments, derived from Units III and IV, migrate at 6.0×10^6 Mr as shown by analysis of CBA/St (Table 2; Fig. 5, lane L) in which Unit IV but not III is present and a 6.0×10^6 MW fragment is still observed.

§ These units have not been characterised fully by biochemical techniques.

¶ The 3.0 *Eco*RI fragment is inferred from the broadening of the 4.0 band (see lane G compared with lane I in Fig. 5).

** This small molecular weight fragment is not included on the gel shown in Fig. 5.

examined here; results with feral mice (see above) indicate that this unit is not, however, ubiquitous in mice. When the genotypes were correlated with the genealogical tree for the mouse colonies used (Fig. 6), three units (I, III, and IV) were found in both major branches of the tree but not in all the members. Unit V was identified in colonies on one branch and in contemporary DBA/2 mice. Unit VI was also found in DBA/2 mice but not in any of the progeny from the original Bagg albino × DBA cross; we cannot say whether it is likely to have been present in the DBA male used in the initial cross. These results indicate that the parental Bagg albino and DBA animals were not both homozygous for any of the defined units of endogenous MMTV DNA, with the probable exception of Unit II; Units I, III, IV, and V (and perhaps VI) have consequently segregated during inbreeding.

MMTV genotypes can be used to monitor breeding programmes

To ensure that the observed results were not the result of errors in breeding protocols, we examined several colonies of some strains maintained at widely separated locations. Colonies of C₃H/He mice maintained at Jackson Laboratories (Bar Harbor), the National Institutes of Health (Bethesda); and the University of California (Berkeley) yielded identical results, as did colonies of C₃H/Bi (and C₃Hf/Bi) from Simonson Laboratories (Gilroy, California), the Sloan-Kettering Institute (New York), and the Imperial Cancer Research Fund (London) (data not shown).

An interesting exception to the general rule of identity among separately maintained colonies was provided by the differences in genotype between the C₃H/St mice maintained at the L.C. Strong Foundation (San Diego, California) and a subline, C₃H/StWi, derived in 1947 by Wilson from the original Strong colony²³ and maintained at the National Institutes of Health (Bethesda); Unit IV is present in the colony derived by Wilson but not in that kept by Strong (data not shown). Since these colonies were separated in the 1940s it is probable that the animals were not fully inbred at that stage and were heterozygous with respect to Unit IV. It is, of course, also possible that Unit IV either was lost from the Strong colony as a consequence of deletion or introduced into the Wilson subline by an inadvertent interruption in the pedigree.

In view of the result with C₃H/St, we looked for evidence of incomplete inbreeding or genetic instability in the contemporary colony of C₃H/St at San Diego by testing the DNA from several individuals for endogenous MMTV DNA. So far no differences

have been observed among members of this colony, in tests that have included 20 individuals. In addition, analysis of endogenous MMTV sequences among numerous BALB/c colonies has not revealed any differences. These results suggest that contemporary mouse strains are truly homozygous at most or all viral loci, as predicted from other kinds of analysis²², and that endogenous MMTV DNA seems stable by the criteria which revealed marked heterogeneity among feral mice. Such tests for defined patterns of endogenous viral DNA may be a particularly sensitive assay for the success of an inbreeding programme; for example, we would have been likely to have measured the heterogeneity in C₃H/St at the time of separation of its colonies (see above).

Fig. 5 Products of *Eco*RI digestion of MMTV DNA endogenous to progeny of Bagg albino × DBA. 10 µg of DNA from the livers of individual mice from the strains indicated were digested to completion with *Eco*RI and then analysed as described in Fig. 2 legend. ³²P-labelled *Eco*RI fragments of λ DNA included in the gel were used as MW standards in obtaining $MW \times 10^{-6}$ listed between lanes J and K for major viral fragments. Viral fragments found only in the DBA/2 (lane K) parent strain are presented in the squares while fragments shared by more than one strain are indicated by the larger numbering. Lane A, C₃Hf/Bi; B, C₃H/Bi; C, C₃H/St; D, CBA/N; E, CBA/J; F, CBA/CaJ; G, CBA/Ht-6; H, C₃H/HeJ; I, C₃H/HeN; J, C₃H/An; K, DBA/2; L, CBA/St.

Implications for origins of endogenous DNA

Our results are most readily interpreted as evidence favouring the hypothesis that endogenous proviruses result from multiple, independent, but presumably infrequent infections of germ line tissues with retroviruses. According to this view, the similarities among retroviruses from many species would reflect their probable evolution from a single progenitor virus; the rationale for their ubiquity would be no more obvious than the rationale for the ubiquity of any other of the several far-flung classes of virus; and their appearance as endogenous viruses would be a consequence of their capacity to establish their genomes in infected cells, presumably including germ cells, as proviruses covalently integrated into host cell DNA. Several ancillary observations are in accord with this proposal. (1) The four MMTV proviruses endogenous to the A strain mouse are located on more than two chromosomes²⁴, consistent with their acquisition by multiple, independent infections. (2) Evidence for trans-species transmission of viruses now recovered as endogenous viruses argues that they were established by infection of germinal tissues^{5,25,26}. (3) Avian leukosis virus-specific DNA cannot be detected in two types of wild jungle fowl, despite its presence in a third type of jungle fowl, in closely related domestic chickens, and in more distantly related pheasants (D.

Table 2 Genotypes observed in progeny of Bagg albino × DBA

Genotype designation	Units of MMTV DNA	Example
	I II III IV V VI	
A	+ + - + + +	DBA/2 (Figs 4L, 5K)
B	+ + - + - -	CBA/St (Figs 4M, 5L)
C	+ + + - - -	BALB/c (Figs 2A, 3B, 4K)
D	+ + + + - -	C ₃ H/Bi (Figs 4A, 5B)
E	- + + - - -	CBA/CaJ (Figs 4D, 5F)
F	+ + - - + -	C ₃ H/HeN (Figs 4F, 5I)

The units of endogenous MMTV DNA defined in Table 1 were sought by examination of *Pst*I and *Eco*RI digests of liver DNA from mice in colonies derived from Bagg albino × DBA (see Figs 4, 5). The presence of a unit is indicated by +, its absence by -. Six genotypes, designated, A, B, C, D, E, and F, were observed in the tested samples. An example for which complete data are provided is listed for each genotype.

Fig. 6 Segregation of endogenous MMTV proviruses during inbreeding of progeny of Bagg albino $\times$ DBA. The genealogy of mouse strains was derived from the summary prepared by Staats²¹ and plotted against the recorded dates for mating and segregation. Solid lines are used for the progeny of the Bagg albino $\times$ DBA mating; dashed lines indicate the ancestors of contemporary BALB/c and DBA colonies, but are not meant to imply that the animals involved in the indicated cross were the direct predecessors of BALB/c and DBA/2 mice used here. The genotype (see Table 2) for each strain examined was determined from analyses of the sort shown in Figs 4 and 5 and is noted below the name of the strain.

* Not done because the strain was not available.

† C3H/St is assigned 'C or D' because two colonies gave different results (see text).

Frisby, R. Weiss, M. Roussel and D. Stehelin, personal communication). The lack of concordance of viral DNA with established phylogenetic relationships again argues for infection of germ lines after speciation. (4) Biochemical studies of normal chickens^{27,28} and mice^{29,30} indicate considerable heterogeneity from animal to animal^{27,28} or from strain to strain^{29,30} with respect to the amount and/or structure of endogenous leukaemia virus-related DNA. There is, however, one notable difference between results reported here and the results of studies of endogenous avian leukosis virus-specific proviruses in domestic chickens: all of the tested chickens shared one common proviral element, despite the variable distributions of other elements^{27,28}. This observation might mean that domestic chickens have been derived from a relatively small genetic pool, or it might imply that a least one provirus was introduced into the germ line of chickens at some relatively early time. (5) In the studies of avian viruses, the variability in number, location, and structure of endogenous proviruses contrasted with uniform or nearly uniform results obtained with reagents specific for cellular genes, such as globin, ovalbumin, ovomucoid, and transferrin²⁷; these findings further support the thesis that endogenous proviruses either originate or evolve in a manner fundamentally different from cellular genes.

Our results obviously run counter to the widely held view that endogenous viral DNA has evolved either from some ancient cellular sequences⁴ or from an ancient provirus present in early vertebrates⁵. This point of view has encouraged examination of the relatedness of endogenous proviruses in attempts to assess the evolutionary relationships among many animals³¹, including man³². The proposal favoured by our data, if supported by similar studies of other kinds of proviral DNA, would challenge the assumptions that underlie such studies. Certainly it is possible that some kinds of proviral DNA other than MMTV DNA appeared in germ lines, by infection or other mechanisms, sufficiently long ago to serve as useful markers for vertebrate evolution. In addition, interpretation of our data would be difficult if retroviral DNA exhibits a propensity to undergo deletion, rearrangement, or translocation. Although our results with the progeny of Bagg albino $\times$ DBA mice argue for stability of germinal proviral elements over a 60-yr period, we cannot discount rare events of these kinds over a much longer period as explanations for some or all of our observations with feral mice. Future experiments with other endogenous proviruses and with proviruses acquired by infection of cultured cells may be helpful in judging such possibilities.

Implications for mammary tumorigenesis

The hypothesis that endogenous proviruses arise by infection rather than by conservative evolution from sequences common to primitive vertebrates does not favour any functional role for viral DNA in the growth and development of normal organisms. Nevertheless endogenous viral DNA may significantly alter

major biological processes in ways that have yet to be recognised; certainly its presence may have pathological consequences for the host animal. This idea has been dramatically documented in the laboratory by the markedly increased frequency of leukaemia in BALB/c mice following the introduction of the provirus of the Moloney strains of murine leukaemia virus as an endogenous provirus³³. In the case of MMTV, the GR strain is apparently prone to early mammary tumours⁷ as a consequence of its carriage of endogenous provirus(es) indistinguishable in tests described here from that acquired by infection with milk-borne virus of known oncogenic potential (our unpublished data). The GR mouse may be a special case, in that the provirus in question seems to be present in multiple, probably closely-linked copies^{9,10,34,35}. The biological effects of a similar endogenous provirus (Unit IV) present in some of the mice studied here remains to be determined. It is known, however, that several strains of mice develop mammary tumours late in life under the influence of genetically transmitted viruses⁶⁻⁸; examination of the DNA from such tumours by methods described here indicates that the tumour cells bear additional copies of proviruses similar to that endogenous provirus termed Unit II (our unpublished data). Presumably some alteration in the control of expression of such proviruses results in virus spread and subsequent tumorigenesis, with the pathogenic potential of the element augmented when it is integrated into a new site after secondary infection. A similar mechanism has been proposed to account for the regulation of expression of an endogenous virus of chickens³⁶. This suggests that the site at which an endogenous provirus is integrated in cellular DNA may have a considerable influence upon its expression; depending upon the consequences of viral gene expression for the host, the entry of new proviruses into the germ line at certain sites could therefore provide a selective advantage or disadvantage to the host.

We thank J. Majors, P. Shank, S. Hughes, D. Robertson, and J. M. Bishop for useful discussions; M. Gardner, J. Levy, E. Boyse, C. Dickson, R. Cardiff, S. Nandi, and C. Hansen for materials; M. Fried, E. Southern, C. Dickson, and R. Erickson for critical readings of the manuscript; Vera Varmus for trapping the specimen used in Fig. 1, lane G; and support by USPHS grant CA 12705, CA 19287, CA 21454 and ACS grant VC 70. The nucleotide sequence of a 1,091-base pair cloned cDNA insert encoding bovine corticotropin- β -lipotropin precursor mRNA is reported. The corresponding amino acid sequence indicates that the precursor protein consists of repetitive units and includes a third melanotropin sequence in its cryptic portion. Pairs of lysine and arginine residues separate the component peptides of the precursor.

THE pituitary hormones corticotropin (ACTH) and β -lipotropin (β -LPH) and their gene provide a useful system for studying the structure and regulation of hormonally regulated genes. These two hormones, which are formed from a large common precursor protein¹⁻⁸, contain small component peptides with biological activity; α -melanotropin (α -MSH) and corticotropin-like intermediate-lobe peptide (CLIP) are derived from ACTH⁹, whereas γ -lipotropin (γ -LPH), β -melanotropin (β -MSH), endorphins and methionine-enkephalin are elaborated from β -LPH^{10,11}. The intracellular level of the mRNA coding for the common precursor protein is depressed by glucocorticoids, which probably act at the transcriptional level by means of the glucocorticoid receptor^{12,13}. As ACTH and β -LPH together account for only one-third to one-half of the molecular weight of the precursor protein, there has been considerable interest in and speculation about the primary structure and possible biological functions of the remaining portion.

Recently developed techniques of DNA cloning¹⁴ and nucleotide sequence analysis^{15,16} together provide a useful approach to an understanding of the primary structure of eukaryotic genes and the regulation of their expression. Previously¹⁷, we described the construction of bacterial plasmids that contain the nucleotide sequence for the bovine ACTH- β -LPH precursor and presented the DNA sequence coding for ACTH and a portion of β -LPH. Here, we report the complete nucleotide sequence of a 1,091-base pair cloned cDNA insert that contains a duplex copy of the ACTH- β -LPH precursor mRNA. Our results define the precise locations of ACTH and β -LPH in the precursor protein and predict the amino acid

sequence of its remaining portion. They further indicate that the precursor protein consists of several repetitive units separated by pairs of basic amino acid residues, lysine and arginine, and that a third melanotropin sequence is located within the cryptic portion of the molecule.

Sequencing strategy

The bacterial plasmid pSNAC20 was constructed by inserting *in vitro*-synthesised double-stranded cDNA for the bovine ACTH- β -LPH precursor into the *Pst*I endonuclease cleavage site of the plasmid pBR322 with the use of poly(dG)·poly(dC) homopolymeric extensions¹⁷. Nucleotide sequence analysis of the inserted cDNA was carried out by the procedure of Maxam and Gilbert¹⁵; the sequence map is shown in Fig. 1. The restriction fragments used were obtained either from intact pSNAC20 or from the cDNA insert (including poly(dG)·poly(dC) tails), which was isolated by cleavage of the plasmid at the regenerated *Pst*I sites¹⁷.

For accurate prediction of the amino acid sequence of the cryptic portion of the ACTH- β -LPH precursor protein, the nucleotide sequence was determined on both strands of the cDNA for all but 33 residues corresponding to the 5' end and 47 residues corresponding to the 3' end of the mRNA; for these regions this was technically difficult, but the sequence data were reliable. In addition, care was taken to overlap the sequence data derived from different endonuclease-generated fragments. These procedures provided a useful verification of the sequence. Furthermore, some of the endonuclease-generated fragments were analysed for nucleotide sequence in duplicate or in triplicate. Thus, at least three sets of sequence data were obtained for all segments of the cloned cDNA, thus eliminating any ambiguity resulting from closely lying bands of chemically degraded DNA, which were occasionally observed on electrophoretic analysis.

Another potential problem in the use of cloned cDNA for sequence analysis of mRNA is a possible error caused by deletion, addition or rearrangement of nucleotides during *in vitro* cDNA synthesis or DNA cloning itself¹⁸⁻²⁰. Thus, an independent method, such as analysis of protein sequence or mRNA sequence, should preferably be used to verify that the

Fig. 1 Sequence map for the cDNA insert in the pSNAC20 plasmid. Nucleotide residues are numbered in the direction from 5' to 3' in the message strand, beginning with the first residue in the coding region for ACTH, and the nucleotides on the 5' side of residue 1 are indicated by negative numbers. The wavy lines represent the poly(dG)·poly(dC) tail of the cDNA insert (27 and ~100 base pairs long on the left and right sides, respectively). The coding regions for ACTH and β -LPH are indicated by closed boxes. Only the restriction sites used for sequencing are shown and are identified by numbers indicating the 5'-terminal nucleotide generated by cleavage. DNA sequence analysis was carried out by the procedure of Maxam and Gilbert¹². The direction and extent of the sequence determinations are indicated by horizontal arrows α -z and α -y. The 5'-end-labelled restriction fragments used for sequencing, which were derived either directly from intact pSNAC20 or from the cDNA insert obtained by cleavage of the plasmid with PstI followed by electrophoretic isolation, were prepared as follows (the letters in parentheses refer to the horizontal arrows, the labelled site is designated by an asterisk, and the number indicates the fragment chain length in base pairs): α , Cleavage of pSNAC20 with EcoRI, labelling, cleavage with PstI, isolation of *EcoRI-PstI-645 (a) and *EcoRI-PstI-570 (b). β -c, Cleavage of pSNAC20 with SmaI, labelling, cleavage with EcoRI, isolation of *SmaI-EcoRI-1,241 (c), *SmaI-EcoRI-160 (d) and *SmaI-EcoRI-4,100 (e). β -f-h, Cleavage of pSNAC20 with AyoI, labelling, cleavage with PstI, EcoRI or PstI, isolation of *AyoI-PstI-223 (f), *AyoI-EcoRI-162 (g) and *AyoI-PstI-430 (h). β -i, Cleavage of pSNAC20 with HaeIII, labelling, cleavage with PstI, isolation of *HaeIII-PstI-975 (i) and *HaeIII-PstI-240 (j). β -k-p, Cleavage of the cDNA insert with AyoI, labelling, isolation of *AyoI-PstI-106 (k), *AyoI-PstI-150 (l), *AyoI-PstI-553 and *AyoI-PstI-340 (the PstI site was not accurately labelled), cleavage of *AyoI-PstI-553 with SmaI, isolation of *AyoI-SmaI-579 (m), cleavage of *AyoI-PstI-340 with TceI, isolation of *AyoI-TceI-105 (n) and *AyoI-TceI-235, labelling of *AyoI-TceI-235, cleavage with HaeIII, isolation of *AyoI-HaeIII-52 (o) and *TceI-HaeIII-183 (p). β -q-y, Cleavage of the cDNA insert with AyoI, labelling, isolation of *AyoI-PstI-245 (q), *AyoI-PstI-710 (r), *AyoI-PstI-147 (s) and *AyoI-PstI-121 (t) (in one experiment, *AyoI-PstI-245 was cleaved with AyoI, and *AyoI-PstI-139 (z) was isolated, alkali treatment²³ of *AyoI-PstI-147, isolation of single-stranded *AyoI-PstI-147 (u) (in one experiment, *AyoI-PstI-147 was cleaved with HaeIII, and *AyoI-HaeIII-40 (v) was isolated), cleavage of *AyoI-PstI-121 either with HaeIII or with SmaI, isolation of *AyoI-HaeIII-49 (w), *AyoI-HaeIII-59 (x) and *AyoI-SmaI-93 (y). β -z, Cleavage of the cDNA insert with AyoI, isolation followed by cleavage with HaeIII of AyoI-PstI-245, isolation followed by labelling of HaeIII-HaeIII-123, cleavage with HaeIII, isolation of *HaeIII-HaeIII-112 (z). α , Cleavage of the cDNA insert with AyoI, isolation followed by cleavage with HaeIII of AyoI-PstI-710, isolation followed by labelling of HaeIII-HaeIII-162, cleavage with EcoRI, isolation of *HaeIII-EcoRI-138 (a). β , Cleavage of the cDNA insert with EcoRI, isolation followed by cleavage with TceI of EcoRI-PstI-645, isolation followed by labelling of TceI-PstI-441, cleavage with HaeIII, isolation of *TceI-HaeIII-270 (b). γ , Cleavage of the cDNA insert with TceI, isolation followed by cleavage with HaeIII of TceI-PstI-441, labelling, cleavage with HaeIII, isolation of *HaeIII-HaeIII-110. Cleavage with restriction endonucleases was carried out as the conditions described by the vendors with optimal amounts of the enzymes. Separation of the restriction fragments was carried out by electrophoresis on either 5% or 8.3% polyacrylamide slab gels in 50 mM Tris-borate containing 1 mM EDTA (pH 8.3), except that alkali-treated *AyoI-PstI-147 was electrophoresed on 15% gel for strand separation. Fractionated DNA was extracted from the gel by maceration. Treatment of DNA with 7 μ g of bacterial alkaline phosphatase (Worthington) was carried out at 55 °C for 1 h in 20 mM Tris-HCl (pH 8.3). Labelling of DNA was carried out at 37 °C for 1 h with 200–250 μ Ci [γ -³²P]ATP (~7,000 Ci mmol⁻¹, New England Nuclear) and 0.5 μ g of T4 polynucleotide kinase (Boehringer-Mannheim Corporation) in a reaction mixture containing 50 mM Tris-HCl (pH 9.5), 10 mM MgCl₂, 5 mM dithiothreitol and 0.75 mM spermidine.

cloned cDNA we have studied represents an exact copy of the mRNA. However, the fidelity of cDNA cloning in bacterial plasmids has been amply established for several mRNA species^{21–26}. We have also obtained evidence indicating that the coding regions for the known segments of the precursor protein (that is, the segments containing ACTH and β -LPH) are faithfully represented in the cloned cDNA (see below). In any case, the conclusions reported here result from study of the cDNA copy of a single mRNA molecule and heterogeneity of the ACTH- β -LPH precursor mRNA cannot be excluded.

Sequence of ACTH- β -LPH precursor mRNA and assignment of protein sequence

Figure 2 gives the sequence of 1,091 nucleotides comprising the cDNA inserted in the bacterial plasmid pSNAC20 (excluding poly(dG)·poly(dC) tails). Our previous work has demonstrated that the sequence of nucleotide residues 1–207 corresponds precisely to the amino acid sequences determined for bovine ACTH and the first portion of bovine β -LPH (28 amino acid residues) plus the two amino acid residues Lys-Arg connecting the two peptides¹⁷. The nucleotide sequence we have determined for the remaining portion of β -LPH indicates the presence of two additional amino acid residues, Ala-Glu, between positions 35 and 36 of the generally accepted structure of bovine β -LPH²⁷. Thus, our results are consistent with a structure of bovine β -LPH that contains 93 amino acid residues, as reported by Pankov²⁸; however, our finding that the residue at position 16 is Gln agrees with the assignment at this position made by Li *et al.*²⁷.

The nucleotide residues encoding the glutamine at the carboxyl terminus of β -LPH are followed by the translational termination codon UGA. This observation indicates that there is no peptide extension beyond the carboxyl terminus of β -LPH and that the 3' noncoding region of the mRNA is composed of an untranslated region of 175 nucleotides plus a poly(A) terminal sequence. Another significant finding is that the amino terminus of ACTH, like the carboxyl terminus, is connected to the adjacent peptide by a pair of basic amino acid residues, Lys-Arg. Thus, the formation of ACTH and β -LPH from their precursor seems to involve proteolytic processing similar to that observed in the conversion of proinsulin to insulin²⁹ and parathyroid hormone to parathyroid hormone^{30,31}.

In assigning the amino acid sequence of the cryptic portion of the ACTH- β -LPH precursor, the reading frame of amino acid codons was determined from the frame corresponding to the amino acid sequences of ACTH and β -LPH. However, the translational initiation site on this mRNA cannot be located definitively without knowing the amino acid sequence of the amino-terminal region of the precursor protein. A possible location for the translational initiation site is the methionine codon AUG at positions –393 to –391. On the basis of this assignment, the molecular weight of the ACTH- β -LPH precursor protein is calculated to be 29,259, a smaller value than the previously estimated molecular weight of the cell-free translation product of bovine ACTH- β -LPH precursor mRNA (35,000 (ref. 1) or 41,000 (ref. 2) depending on the electrophoresis system used). However, the relatively large number of basic amino acids (lysine and arginine) encoded by this mRNA (Fig. 2) or possible glycosylation of the cell-free trans-

lation product may result in overestimation of the molecular weight of the protein by electrophoretic analysis³². The assignment of the translational initiation site at the methionine codon mentioned above seems plausible because the first 20 amino acid residues starting with this putative initiative methionine (residue -131), which are followed by the characteristic sequence Ser-Met-Glu--- (see below), include a large number of hydrophobic amino acids (13 nonpolar residues including 7 leucine residues). A high content of hydrophobic amino acids is known to be present in the signal peptides of other proteins destined for secretion³³⁻³⁶. On the other hand, if the previous estimation of the molecular weight of the precursor protein is correct, the translational initiation site would be located 1,125-1,295 nucleotides (950-1,120 nucleotides for the coding region plus the 175 noncoding nucleotides we have identified at the 3' end) away from the first residue of the poly(A) sequence of the mRNA and therefore would be absent from the cloned cDNA segment we have analysed. In Fig. 2, we have assigned amino acid residues up to the putative initiative methionine, although it remains possible that the region of the mRNA proximal to this site is translated.

Computer analysis of the amino acid sequence determined from the pSNAC20 clone indicates that the sequence of amino acid residues -55 to -44 is strikingly similar to the sequences of α -MSH and β -MSH, which are known to have common structural and biological features³⁷ (Fig. 3). This segment of the precursor protein shares with the known MSHs tyrosine and methionine residues as well as the characteristic tetrapeptide sequence His-Phe-Arg-Trp, which is required for melanotropic activity, at equivalent positions³⁸. Moreover, the peptide fragment discovered by our DNA sequence analysis is flanked on both sides by a pair of basic amino acid residues. This suggests that the new peptide, like α -MSH or β -MSH, can be formed by proteolytic processing of the precursor; by analogy with α -MSH, it is possible that phenylalanine amide is formed at the carboxyl terminus of this peptide during processing. In view of the remarkable structural homology between the newly found peptide fragment and α -MSH or β -MSH, we propose to name the peptide γ -melanotropin (γ -MSH). Another peptide fragment within the precursor protein that exhibits some structural similarity to the MSHs is that containing amino acid residues -111 to -105 (Fig. 3). Note that this fragment contains

Fig. 2 Primary structure of bovine ACTH- β -LPH precursor mRNA. The nucleotide sequence of the ACTH- β -LPH precursor mRNA was deduced from that of the cDNA insert in pSNAC20. The nucleotide numbers (see legend to Fig. 1) are indicated below the sequence. The predicted amino acid sequence up to the methionine residue encoded by nucleotide residues -393 to -391 is shown above the nucleotide sequence. Amino acid residues are numbered in the direction from amino terminus to carboxyl terminus, beginning with the first residue of ACTH, and the residues on the amino-terminal side of ACTH are indicated by negative numbers, the amino acid numbers are given above the sequence. The sequence of nucleotide residues 1-207 was reported previously¹⁷ and was confirmed by sequencing additional restriction fragments as shown in Fig. 1. The cDNA insert includes a poly(A) tract of eight nucleotides at positions 578-585, but the average length of the poly(A) sequence in the mRNA was previously estimated to be 68 nucleotides.

methionine and tryptophan residues at the positions characteristic of the MSH structure and shares with α -MSH serine and glutamic acid residues at equivalent positions. Computer analysis indicates no structural correspondence of other amino acid sequences in the cryptic portion of the precursor with hormones of known sequence³⁹.

From the findings described above, we conclude that the ACTH- β -LPH precursor protein is probably composed of four repetitive structures as shown in Fig. 4. Each unit contains a homologous peptide core segment having an MSH sequence or its analogue, which is followed by or lies within an individually different sequence. Furthermore, each of the repetitive units, as well as the MSH sequences themselves, is flanked on both sides by a pair of basic amino acid residues (or by one of the termini of the precursor molecule). The putative structure of the common precursor protein suggests that each of its units is destined to be separated from its neighbour by proteolytic processing and that further cleavage occurs within the unit to yield smaller peptides.

The peptide fragment consisting of amino acid residues -131 to -58 includes five cysteine residues, and the remainder of the precursor molecule contains no cysteine residue. Other peptide hormones, such as growth hormone and insulin, contain an even number of cysteine residues which form disulphide bonds³⁹. Thus, we can assume that the cysteine residue at position -127 is a constituent of the putative signal peptide, which is removed during the process of secretion, although we cannot exclude the possibility that an odd number of cysteine residues are encoded by the missing portion of the mRNA.

The repetitive nature of the amino acid sequence of the ACTH- β -LPH precursor molecule raises interesting questions concerning both the biological significance of its characteristic structure and the biological functions of possible peptide fragments that may be derived from it. The presence of several partly homologous units within the same molecule suggests that the functions of the component peptides may be related to or coordinated with one another. It is well established that ACTH is essential for the induction and maintenance of glucocorticoid production in adrenocortical cells⁴⁰. However, additional pituitary effects on adrenocortical cells, such as stimulation of mitogenic activity and mineralocorticoid production, cannot be accounted for solely by the action of ACTH⁴⁰. It is an intriguing hypothesis that other peptides which may be elaborated from the precursor molecule are involved in these actions. Another possibility is that these structurally related peptides are involved in neural functions. Several studies have demonstrated that not only endorphins and methionine-enkephalin⁴¹ but also MSHs and related peptides^{42,43} are present in various regions of the central nervous system. In addition to the potent opiate activity of endorphins and methionine-enkephalin⁴⁴, MSH-related peptides have been reported to exert certain effects on brain function, such as learning and retention of new behaviour⁴⁵. Thus, it is attractive to speculate that various peptides derived from the ACTH- β -LPH precursor may act together or antagonistically as modulators of neural functions.

Table 1 Codon usage in bovine ACTH- β -LPH precursor mRNA

The amino acid sequence of the bovine ACTH- β -LPH precursor has been predicted solely from the nucleotide sequence of the mRNA, assuming that the translational initiation site is located at the methionine residue at position -131. Numbers next to codons indicate the numbers of amino acids using particular codons.

Characteristic features of ACTH- β -LPH precursor mRNA

We have previously observed that the coding regions for ACTH and the first segment of β -LPH contain an unusually large number of repeated nucleotide sequences, suggesting that these regions of the structural gene for the ACTH- β -LPH precursor have evolved by a series of genetic duplications¹⁷. In the present study, this observation has been extended to the remaining portions of the ACTH- β -LPH precursor mRNA. Comparison of the coding regions for α -MSH, β -MSH and γ -MSH strongly supports the view that DNA sequence duplications have occurred during the evolution of these genes (Fig. 3). The nucleotide sequences encoding the common amino acids are conserved, except for a very few silent codon changes; however, those coding for the amino acids that are different in the three peptides are drastically altered. In addition to showing the extensive nucleotide sequence homology just mentioned, computer analysis^{46,47} of the nucleotide sequence data presented in Fig. 2 reveals that the ACTH- β -LPH precursor mRNA contains other segments that seem to represent direct duplications; for example, residues -453 to -443 and 406 to 417; -93 to -82 and 235 to 246; -65 to -54 and 35 to 45; -11 to -2 and 299 to 308; 163 to 187 and 220 to 241; 400 to 411 and 506 to 517. Taken together, these findings support our concept that the structural gene for the ACTH- β -LPH precursor protein has evolved by a series of direct duplications of certain common ancestral DNA segments followed by substitution, addition or deletion of some regions.

Codon choices for the ACTH- β -LPH precursor mRNA have been assigned (Table 1), using the amino acid sequence shown in Fig. 2. No definitive conclusion can be reached concerning codon utilisation because the initiation site for translation has not been established. Nevertheless, codon usage seems to occur nonrandomly, as in the case of other eukaryotic mRNAs²¹⁻²⁵, and specific codon choices seem to be strongly preferred for

Fig. 3 Comparison of nucleotide and amino acid sequences in the regions including MSHs and their analogues. The amino acid sequences are lined up, introducing gaps so as to point out the homologous domains in the text, for the numbering of nucleotide and amino acid residues, see legends to Figs 1 and 2. The amino acid residues in solid-line boxes occur in at least three of the four structures shown and those in dashed-line boxes are found in two of them. Sequences of two or four consecutive basic amino acid residues are underlined. α -MSH³⁹ represents amino acid residues 1-13, of which the serine residue at position 1 is N-acetylated and the valine residue at position 13 is in the form of an amide, β -MSH³⁹ represents amino acid residues 54-

Fig. 4 Schematic representation of the structure of bovine ACTH- β -LPH precursor. Characteristic amino acid residues are shown, and the positions of the methionine, tryptophan and cysteine residues are given in parentheses, for the numbering of amino acid residues, see legend to Fig. 2. The location of the translational initiation site at the methionine residue at position -131 is assumed (see the text). The closed bars represent the regions for which the amino acid sequence was known, and the open and the shaded bars represent the regions for which the amino acid sequence has been predicted from the nucleotide sequence of the ACTH- β -LPH precursor mRNA. The locations of known component peptides are shown by closed bars; the amino acid numbers are given in parentheses. The locations of γ -MSH and the putative signal peptide are indicated by shaded bars; the termini of these peptides are not definitive.

some amino acids. Certain codons (for example, UUC for Phe, CUG for Leu, AAG for Lys) are used repeatedly, whereas other codon choices are either not made or are rare (for example, UUA for Leu, AUA for Ile, GUA for Val). This mode of codon selection reflects an apparent preference for G or C of the third position of mammalian codons²¹⁻²⁴. Assuming that the initiation site is located at the methionine residue at position -131, 116 codons (44%) terminate in G, 112 (42%) in C, 26 (10%) in U and 11 (4%) in A.

Reflecting the selective codon usage, the ACTH- β -LPH precursor mRNA (excluding the poly(A) region) has a high G+C content (65%) which exceeds that of total bovine DNA (39%)⁴⁸. Also, this mRNA exhibits nonrandom dinucleotide frequencies. The abundance of the dinucleotide CG in this mRNA exhibits a marked contrast to its deficiency in other eukaryotic mRNAs²¹⁻²⁵ as well as in total bovine DNA⁴⁹.

The 3' noncoding region of the ACTH- β -LPH precursor mRNA also shares some features with other eukaryotic mRNAs^{21-25,50}. A lengthy inverted repeat (that is, region of two-fold rotational symmetry) exists at nucleotide residues 469-

492 and 521-497, and this inverted repeat follows two in-frame copies of the nonsense codon UGA. Similar sequence features have been reported for the 3' noncoding end of human chorionic somatomammotropin mRNA⁵¹. Also, the sequence AAUAAA (residues 555-560), which is commonly present near the 3' noncoding end of eukaryotic mRNAs, is found in the corresponding region of the ACTH- β -LPH precursor mRNA.

The sequencing data are available from the authors on request.

We thank Drs M. Takanami and K. Sugimoto for their advice and for gifts of some restriction endonucleases, and Dr T. Honjo for advice. The investigations carried out in Kyoto were supported in part by research grants from the Ministry of Education, Science and Culture of Japan, the Mitsubishi Foundation, the Foundation for the Promotion of Research on Medicinal Resources, and the Japanese Foundation of Metabolism and Diseases. The studies at Stanford were supported by grants to S.N.C. from the NIH, the American Cancer Society, and the NSF.

‡ To whom correspondence should be addressed

A clone which contains the complete chicken ovalbumin gene, including its leader coding sequences, has been isolated. From electron microscopic analysis of this DNA we conclude that the minimal size of the transcriptional unit for ovalbumin is 7.7 kilobases. The DNA sequence of the region surrounding the 5' end of the ovalbumin gene is presented. Comparison of this sequence with those of other eukaryotic genes reveals striking similarities, possibly related to a promoter region, approximately 30 base pairs upstream from the site coding for the 5' end of the mRNA.

coding regions (exons 1 to 7) are contained in a DNA region of about 6 kilobases and are separated by six introns (B to G) (refs 6–8, and Fig. 1b). A similar conclusion has been reached by Dugaiczky *et al.*⁹. However, the first 45 nucleotides at the 5' end of the 1,872-nucleotide long ov-mRNA^{10,11} are not encoded by sequences contained in exon 1 or in *Eco*RI fragment 'b' upstream from exon 1 (ref. 12). We have called¹² this untranslated sequence of 45 nucleotides the ovalbumin leader, by analogy with the viral terminology. We have assumed that the leader-coding sequences are located upstream from the *Eco*RI site *Eco*4 and are separated from exon 1 by an additional intron A (ref. 12 and Fig. 1b). Thus, the determination of the localisation of the DNA segment containing the leader-coding sequences and its purification are prerequisites for the study of the molecular mechanisms involved in the transcription of the ovalbumin gene and its hormonal control. We report here the isolation of chicken genomic DNA clones which contain a complete ovalbumin gene including the region coding for the ov-mRNA leader. The position of the leader-coding sequences has been determined by electron microscopy and DNA

DUE to molecular cloning, our knowledge of the structure of the chicken ovalbumin gene has advanced rapidly since we first reported that this gene is split¹. The ovalbumin genomic *Eco*RI fragments (*Eco* 'a', *Eco* 'b' and *Eco* 'c', Fig. 1b) have been cloned and analysed^{2–3}. Seven ovalbumin mRNA (ov-mRNA)

Fig. 1 Organisation of the ovalbumin gene. a, Scale in kilobase pairs for (b). b, Localisation of the exons (1 to 7, heavy lines) and introns (A to G) of the ovalbumin gene in λ C4-ov5 and λ C4-ov6 within and upstream from the *Eco*RI fragments *Eco* 'a', *Eco* 'b' and *Eco* 'c'. The horizontal dotted line represents λ Charon 4A sequences. The uninterrupted and dashed arrows indicate the limits of the 16.7 and 9.8 kilobase genomic DNA fragments inserted in λ C4-ov5 and λ C4-ov6, respectively. L corresponds to the location of the leader-coding sequences as determined by electron microscopy and DNA sequencing (see text). The *Eco*, *Pst*, *Hind* and *Hha*I sites correspond to *Eco*RI, *Pst*I, *Hind*III and *Hha*I restriction enzyme sites which were mapped in this study or previously (refs 7, 12). c, Localisation of *Pvu*II, *Taq*I, *Hae*III (*Hae*), *Apa*II, *Hind*III (*Hind*), *Eco*RI (*Eco*) and *Hinf*I (*Hinf*) restriction enzyme sites within the *Pst*3–*Pst*4 fragment of b. L, A, B, C, D, 1, 2, 3 and 4 are as described for b. d, Schematic representation of the electron microscopic result shown in Fig. 3c and correlation with the restriction enzyme map shown under c. The heavy lines L, 1, 2, 3 and 4 represent the RNA-DNA hybrid regions corresponding to the leader-coding regions (L) and to exons 1 to 4, respectively. A, B, C and D correspond to the intronic single-stranded loops A, B, C and D, respectively. The numbers correspond to base pairs or nucleotides and were calculated from measurement of 51 molecules of the type shown in Fig. 3c. e, Schematic representation of ov-mRNA. The total length and the position of the AUG and UAA codons are taken from refs 10–12. L refers to the leader sequence and 1 to 7 correspond to the seven domains of ov-mRNA coded by exons 1 to 7. The arrows indicate the limits of these domains, assuming that the splicing events obey the GT-AG rule (see ref. 12 and text). Numbers in parentheses indicate the length (in nucleotides) of the domains.

sequence analysis. The sequences preceding those coding for the 5' end of ov-mRNA have also been determined and compared with those of other genes in a search for possible regulatory signals.

Isolation and mapping of ovalbumin clones containing sequences upstream from exon 1

A chicken erythrocyte DNA library has been constructed by J. Dodgson, D. Engel and R. Axel using a method described by Maniatis *et al.*¹³. Briefly, this approach consists of partially digesting the DNA by *HaeIII* and *AluI* restriction enzymes, selecting DNA fragments which are 15–20 kilobases long, ligating these fragments to the vector λ Charon 4A using *EcoRI* linkers, and infecting *Escherichia coli*. As the recognition sites for both *HaeIII* and *AluI* occur frequently, a partial digest by these enzymes is analogous to random shearing of the DNA. This library was made available to us, with the indication that it contained 400,000 independent clones.

To limit the number of clones analysed to those most likely to contain the 5' region of the ovalbumin gene, we screened² the library using a nick-translated ³²P-labelled *Eco4-Hind2* fragment (see Fig. 1b) as probe. Four clones containing ovalbumin sequences were isolated by screening about 2×10^6 plaques. Two of these (λ C4-ov5 and λ C4-ov6) were shown by preliminary mapping experiments to contain previously uncloned DNA, upstream from *EcoRI* fragment b, and were selected for further analysis.

We have previously shown^{1,7} that the ovalbumin sequences containing exons 1 to 7 are found in two *HindIII* fragments of about 4.6 and 3.2 kilobases (defined by the *HindIII* sites, *Hind1*, *Hind2* and *Hind3* in Fig. 1b) and in two major *PstI* fragments each of about 4.5–4.6 kilobases (defined by *PstI* sites, *Pst1-Pst2* and *Pst3-Pst4*, Fig. 1b). The DNA of λ C4-ov5 and 6 was digested with *HindIII*, transferred to nitrocellulose filters and hybridised with the ³²P-labelled ovalbumin double-stranded cDNA probe (*Hhaov*), as previously described¹. As shown in Fig. 2A (lanes 2 and 5), both clones contain the two *HindIII* fragments. Only one strongly hybridising band, corresponding to the two large *PstI* fragments, was seen (see legend to Fig. 2A) when the clones were digested with *PstI* (lanes 3 and 6). From these results we conclude that both clones contain all the DNA between sites *Pst1* and *Pst4* (Fig. 1b). In agreement with these results, *EcoRI* fragments 'b' (2.35 kilobases) and 'c' (1.75 kilobases) are present in both clones (Fig. 2A, lanes 1 and 4). However, the 9.2-kilobase fragment *EcoRI* 'a' was replaced in λ C4-ov5 by a 8.4-kilobase band (Fig. 2A, lane 4) and in λ C4-ov6 by a 2.8-kilobase band (lane 1). From these latter results we conclude that the limits of the inserted DNAs at their 3' end are as indicated by arrows at the right-hand side of Fig. 1b.

The DNA of the two clones was digested with *EcoRI* and the fragments stained with ethidium bromide after agarose gel electrophoresis. The results are shown in Fig. 2B. In addition to the two large arms of λ Charon 4A, (bands a and b), fragments of 8.4, 3.2, 2.35, 1.75, 0.5 and 0.45 kilobases were found in the digest of λ C4-ov5 (Fig. 2B, lane 3), whereas fragments of 2.8, 2.5, 2.35, 1.75 and 0.45 kilobases were present in the λ C4-ov6 digest (lane 2). The *EcoRI* fragments of 8.2 (λ C4-ov5), 2.8 (λ C4-ov6), 2.35 and 1.75 kilobases have already been mapped (see above and Fig. 1b). The above results indicate that the other *EcoRI* fragments are necessarily located on the 5' side of the *Eco4* site. Their relative positions in the λ C4-ov5 '*Pst3-Pst4*' fragment (Fig. 1c) which was sub-cloned in pBR 322, were derived by further mapping with *TaqI*, *PvuII*, *HaeIII*, *AvaiI*, *HinfI*, *HindIII* and *EcoRI* enzymes (not shown). We found that the *Pst3-Pst4* fragment contains, in addition to the already known *Eco4* site, two *EcoRI* sites, *Eco5* and *Eco6*, at 0.45 and 0.95 kilobases from *Eco4*, respectively (Fig. 1c). Therefore, there are 3.2 kilobases between *Eco6* to the 5' end of the inserted DNA (Fig. 1b, arrow) to which the *EcoRI* linker was added. Parallel experiments showed that the *EcoRI* site *Eco6* is missing in the DNA fragment inserted in clone λ C4-ov6, which

probably corresponds to an additional allelic form of the ovalbumin gene^{3-5,7,9}. From the size of the *EcoRI* fragments of clone λ C4-ov6, we conclude that the 5' end of the inserted DNA is 2.5 kilobases from *Eco5* (Fig. 1b, dashed arrow).

These analyses indicate that the sizes of the chicken DNA fragments inserted in clones λ C4-ov5 and 6 are 16.7 and 9.8 kilobases, respectively (Fig. 1b). In λ C4-ov5 there are about 10.3 kilobases separating the 5' end of the inserted fragment from the extremity of exon 7, which codes for the 3' end of ov-mRNA. The corresponding distance is 9.2 kilobases in clone λ C4-ov6. Considering these sizes, we expected that these clones should contain the sequences coding for the ov-mRNA leader.

Fig. 2 A, Detection of restriction enzyme fragments which hybridise to the double-stranded ovalbumin cDNA probe ³²P-*Hhaov* (ref. 1), in *EcoRI*, *PstI* and *HindIII* digests of λ C4-ov5 and λ C4-ov6 DNAs. The DNA was digested, electrophoresed on a 1% agarose gel, transferred onto nitrocellulose filters, hybridised with a ³²P-*Hhaov* probe and revealed by autoradiography as previously described¹. Lanes 1, 2 and 3: *EcoRI*, *HindIII* and *PstI* digests of λ C4-ov6 DNA, respectively. Lanes 4, 5 and 6: *EcoRI*, *HindIII* and *PstI* digests of λ C4-ov5 DNA, respectively. Sizes of the hybridising fragments (in kilobases): lane 1, 2.8 (a), 2.35 (b) and 1.75 (c); lanes 2 and 5, 4.5 (a) and 3.2 (b); lanes 3 and 6, 4.5–4.6 (a) (the two fragments of 4.55 and 4.4 kilobases, which were clearly seen on the same gel after ethidium bromide staining, were poorly resolved on the autoradiogram); lane 4, 8.4 (a), 2.35 (b) and 1.75 (c). B, Detection of *EcoRI* restriction enzyme fragments of λ C4-ov5 and λ C4-ov6 DNAs by staining with ethidium bromide after electrophoresis on a 0.8% agarose gel. Lane 1, *BamHI* and *EcoRI* restriction enzyme fragments of adenovirus-2 DNA used as size markers (in kilobases): 21.05 (a), 14.6 (b), 10.4 (c), 6.3 (d), 4.7 (e), 4.4 (f), 3.71 (g), 2.9 (h), 2.05 (i) and 1.87 (j). Lane 2, *EcoRI* digest of λ C4-ov6 DNA; size of the fragments (in kilobases): 19 (a), 12 (b), 2.8 (c), 2.5 (d), 2.35 (e), 1.75 (f) and 0.45 (g). Lane 3, *EcoRI* digest of λ C4-ov5 DNA; size of the fragments: 19 (a), 12 (b), 8.4 (c), 3.2 (d), 2.35 (e), 1.75 (f), 0.55 (g) and 0.45 (h). Lane 4, SV40 DNA fragments of a partial *HindIII* digest used as size markers (in kilobases): 1.77 (a), 1.15 (b), 1.1 (c), 0.52 (d), 0.45 (e) and 0.22 (f). To show clearly bands g and h (lanes 2 and 3) the lower part of the figure was exposed for a longer time.

Electron microscopic mapping of the leader-coding sequences

The heat-denatured DNAs of λ C4-ov5 and 6 were hybridised to purified ov-mRNA at 54.3°C in the presence of formamide in conditions favouring the formation of RNA-DNA hybrids^{2-4,14}. Figure 3a and b are electron micrographs of the hybrid molecules obtained with λ C4-ov5 and λ C4-ov6, respectively. These micrographs show an RNA-DNA hybrid region of $1,893 \pm 114$ base pairs and seven single-stranded DNA loops. The same results were obtained with both clones. The size and relative positions of the DNA loops B to G and of the RNA-DNA hybrid regions 1 to 7 (see line drawings) show that they correspond to the region of the chicken genome which contains the ovalbumin exons 1 to 7 and introns B to G which we have described previously (refs 3-6, 12, and Fig. 1b). The additional single-stranded DNA loop, which was seen in most of the hybrid molecules, must therefore correspond to intron A which was expected to separate exon 1 from the DNA region coding for the ovalbumin mRNA leader.

To map the position of the DNA sequence coding for the leader segment, measurements were made on electron micrographs of hybrid molecules between the *Pst*3-*Pst*4 DNA fragment (see above) and ov-mRNA (Fig. 3c). These results are shown in Fig. 1d and are aligned with the corresponding restriction enzyme map (Fig. 1c). The size of loop A positions the leader-coding sequence at $1,555 \pm 147$ base pairs from the 5' end of exon 1 and $1,267 \pm 152$ base pairs from the *Pst*4 site. In addition, measurements of hybrid molecules similar to those shown in Fig. 3a, b indicate that there are about 7.7 kilobases between the 5' end of loop A and the 3' end of exon 7 (see legend to Fig. 3a).

Fig. 4 Strategy for DNA sequencing in the leader-coding region. The detailed restriction map of the 1,730-base pair *Eco*RI-*Pst*I (*Eco*6-*Pst*4, Fig. 1c) fragment of clone (λ C4-ov5) was established using the technique of Smith and Birnstiel¹⁴ and by digestion of the fragment with various enzymes (indicated), either singly or in combination. The arrows below the sequence show the direction and extent of the sequence determinations.

Although the 5' end of the DNA-RNA hybrid region, responsible for the presence of loop A, was not actually resolved in electron micrographs, because of the small size of the leader segment, the consistency of the above measurements indicates the existence of a specific hybrid region. Moreover, this region must involve ov-mRNA, as no similar loops were obtained with the DNA alone. It is unlikely that the presence of this hybrid region is related to some DNA rearrangement which could have occurred during the cloning, because the same results were obtained with these two λ clones and with the cosmid clone

Fig. 5 Nucleotide sequence surrounding the ovalbumin mRNA leader-coding region and the 5' end of exon 1. The sequences surrounding the leader-coding region were established as outlined in Fig. 4 using the method of Maxam and Gilbert¹⁶ and exemplified in Figs 6 and 7. The sequence around the intron A-exon 1 junction was taken from ref. 12 and our unpublished results. The DNA sequence of the non-coding strand is aligned with the mRNA sequence¹⁰⁻¹². The positive numbers refer to the position of the nucleotides with respect to the 5' end of the mRNA. Negative numbers are given upstream from nucleotide number 1. The repeated dinucleotide AG found at the intron-exon junctions is boxed (see text). The vertical dashed line corresponds to the possible common excision-ligation point. The sequence with high complementarity to the 3' end of the 18S rRNA is indicated by a dotted line (nucleotides 25-33). The total length of intron A is about 1,500 base pairs. The *Alu*I sites predicted within the leader-coding regions from the ov-mRNA sequence are shown.

obtained independently by A. Roy *et al.*¹⁵. In addition, we did not detect any differences in the leader-coding region when we compared the restriction enzyme maps (*Hae*III, *Pvu*II and *Eco*RI/*Pst*I digests) of the cloned λ C4-ov5 and 6 DNAs with those of oviduct or erythrocyte cellular chicken DNAs (data not shown). These latter studies also indicate that no extensive sequences around the leader-coding region are repeated elsewhere in the chicken genome.

Sequences around the leader-coding region

Knowing the approximate position of the leader-coding sequences from electron microscopy, we have mapped in detail the *Pst*4-*Eco*6 region (Fig. 4). We looked for two neighbouring *Alu*I sites separated by about 20 base pairs, the existence of which is known from the sequence of the mRNA leader region¹⁰⁻¹². In fact, two such *Alu*I sites are found between the *Hind*III and *Ava*II sites (Fig. 4). We therefore sequenced this region using the technique of Maxam and Gilbert¹⁶ and our results are shown in Fig. 5. The accuracy of the sequence was ensured by sequencing both strands of the DNA, with the exception of nucleotides -60 to -50. Examples of autoradiograms are shown in Figs 6 and 7.

The sequence coding for the leader of the ovalbumin mRNA is clearly present within the sequenced region (Fig. 5), confirming the electron microscopic data. Furthermore, the results indicate that the leader-coding sequences are not interrupted in the chicken genome. This conclusion is based on the assumption that the ov-mRNA has been sequenced to its 5' extremity. However, this might not be the case, as it has not been

Fig. 3 Electron microscopy of RNA-DNA hybrids. The hybrid molecules were obtained as described in the text. a and b: electron micrographs of hybrids between ovalbumin mRNA and the DNA of λ C4-ov5 (a) and λ C4-ov6 (b). In the insets, ov-mRNA is represented by a dashed line, whereas the solid line corresponds to single-stranded DNA. 5' and 3' arrow heads: 5' and 3' ends of ov-mRNA, respectively, 1 to 7 (the thicker DNA-RNA hybrid regions) correspond to the ovalbumin gene exons, whereas A to G correspond to the seven introns. L is the hybrid region corresponding to the leader-coding sequences. The RNA-DNA hybrid region is $1,893 \pm 114$ base pairs long. The lengths of intronic loops A to G and of the exonic mRNA-DNA hybrid segments 1 to 7 are (in nucleotides or base pairs): 1,560 $\pm$ 147 (A), 238 $\pm$ 45 (B), 601 $\pm$ 35 (C), 411 $\pm$ 58 (D), 1,029 $\pm$ 71 (E), 323 $\pm$ 36 (F), 1,614 $\pm$ 88 (G), 197 $\pm$ 34 (1), 85 $\pm$ 14 (2), 164 $\pm$ 25 (3), 143 $\pm$ 18 (4), 154 $\pm$ 25 (5), 201 $\pm$ 28 (6) and 1,097 $\pm$ 51 (7), respectively. There are about 7.7 kilobases between the 5' end of loop A and the 3' end of exon 7. c: Electron micrograph of a hybrid between ov-mRNA and the cloned *Pst*3-*Pst*4 DNA fragment (see text and Fig. 1b, c). In the inset the dashed and solid lines, 5' and 3' arrow heads, L, 1, 2, 3, A, B, C and D are as described for a and b. P3 and P4 correspond to the *Pst*3 and *Pst*4 ends, respectively (Fig. 1c). The lengths (in base pairs or nucleotides) of the hybrid regions and of the single-stranded DNA loops and L-P4 segment are given in Fig. 1d. The bar corresponds to 0.1 μ m.

possible to sequence the mRNA directly from its 5' end¹⁷. The technique used by McReynolds *et al.*¹⁰ and by O'Hare *et al.*¹¹ to establish the mRNA sequence shown in Fig. 5 involves elongation of a DNA primer hybridised to the 5' end region of the messenger with reverse transcriptase in the presence of chain-terminating dideoxynucleotides. This technique could lead to premature termination if important secondary structure exists in the RNA.

Fig. 6 Autoradiogram of sequencing gel showing the leader sequence. The sequence was read from the strand coding for ov-mRNA. An *HphI*/*HaeIII* fragment (Fig. 4) ³²P-labelled¹² at the *HphI* end was subjected to five base-specific cleavage reactions (G, A>G, C+T, C, A>C) according to the procedure of Maxam and Gilbert¹⁶. The products were analysed on a denaturing gel according to Sanger and Coulson⁴⁵. The numbers (45, 1, -4) indicate the position of the nucleotides corresponding to those shown on the non-coding strand in Fig. 5.

Sequences at the splice points

As shown in Fig. 5, the DNA sequences coding for the 5' end of ov-mRNA are interrupted at a position corresponding to nucleotide 47 of the messenger. This result agrees with our previous work which established that exon 1 does not code for the first 45 nucleotides of the mRNA¹². Nucleotides 46 and 47 (AG) of the messenger could be encoded either by the leader-coding region or by exon 1, due to the presence of the repetition of the dinucleotide AG at both ends of intron A. As previously discussed for the other ovalbumin introns¹², this prevents the definition of a unique splicing point. We have proposed that all intron-exon junctions are closely related and fit the general pattern 5'-TCAGGTA-3' (non-coding strand) at the 5' end of an intron, and 5'-TXCAGG-3' at the 3' end of the same intron¹². Others have stressed this similarity¹⁸⁻²⁰. The additional pair of junctions that we describe here is consistent with this proposal. Moreover, our present results also agree with the 'GT-AG rule' (ref. 12) which allows one to propose unique excision-ligation points common to all introns, despite the existence of the direct repeats. These points are indicated in Fig. 5 by the vertical dotted lines, with dinucleotides GT and AG at the 5' and 3' ends of intron A, respectively. Finally, as for other introns^{12,21}, intron A contains a pyrimidine-rich stretch at its 3' end on the non-coding strand.

The ovalbumin transcription unit

Assuming that no nucleotides were missed when sequencing the 5' end of ov-mRNA, our present studies establish that about 7.7 kilobases separate the genome regions coding for the 5' and 3' extremities of ovalbumin mRNA. Recent *in vivo*²² and *in vitro*²³ studies on primary transcripts from the major late transcription unit of adenovirus-2 strongly suggest that the cap site and the transcription initiation site are coincident and that the initiating residues of the primary transcript are conserved in mRNA as the capped 5' terminus. If, as for adenovirus-2, the ov-mRNA capped sequence identifies the site for the initiation of transcription, the minimal size of the ovalbumin transcription unit should be about 7.7 kilobases. A complete co-linear RNA transcript should then be in the range of 7,700 nucleotides, about four times the size of the mature mRNA. In fact, there is evidence for an ovalbumin gene transcript of approximately this size^{24,25}. Although there is no convincing evidence from these latter studies for ovalbumin RNA molecules longer than this transcript (our previous determination^{8,12} was overestimated due to a problem at that time with RNA size markers of high molecular weights), we cannot exclude the possibility that some processing has already occurred and that the ovalbumin transcription unit is longer than 7.7 kilobases.

Fig. 7 Autoradiogram of sequencing gel showing the sequence upstream from the leader sequence. The sequence was read from the non-coding strand. An *AvaII*/*HindIII* fragment (Fig. 4) ³²P-labelled at the *AvaII* end¹², was sequenced as described in the legend to Fig. 6. The numbers (-55, -32, 1) correspond to the positions of the nucleotides of the non-coding strand as shown in Fig. 5. Cm corresponds to the position of a methyl C which belongs to an *EcoRII* site (G was unambiguously found at this position when the coding strand was sequenced).

Possible control regions

It has been suggested that complementarity between a purine-rich sequence, 3'-UAGGAAGGCGU-5', present at the 3' end of 18S ribosomal RNA and sequences of the 5' non-coding regions of many eukaryotic mRNAs might contribute to mRNA recognition by ribosomes²⁶. As previously noted²⁷, a sequence of nine nucleotides complementary (with one mismatch) to this 18S RNA region is found between positions 25 and 33 of the ovalbumin mRNA (Fig. 5, underlined by dotted line). This sequence is immediately preceded by a region (nucleotides 3-22) which can form a base-paired loop¹⁰. There is no such extensive complementarity with the 3' end of 18S rRNA in the messenger nucleotide sequence located between position 48 and the AUG initiation codon (position 65) and encoded for by exon 1. One can therefore speculate that one of the functions of splicing in the 5' non-coding region would be to transpose such a sequence to the vicinity of the initiation codon. A similar translocation has been described for the adenovirus tripartite leader^{22,28}.

A promoter is functionally defined in prokaryotes as the region of the DNA which precedes a transcription unit and indicates the startpoint for RNA polymerase. Most sequenced prokaryotic promoters have two common interacting sites, the Pribnow box²⁹ and the recognition site³⁰ (for other refs, see refs 31-33). The Pribnow box, which is of the form 5'-TATAATG-3', precedes the transcription-initiation site by five to seven nucleotides and belongs to the model sequence (ref. 32)

where the upper and lower case letters correspond to bases present at high and moderate frequency, respectively (the lower line shows the bases which are most often found as alternatives). The recognition site is a region centred at about 32 base pairs before the beginning of the mRNA and has a structure clearly related to the sequence 5'-TGTTGACATTT-3' (refs 30, 32, 33). Assuming that the ovalbumin mRNA cap site and the startpoint for transcription are coincident, sites analogous to the prokaryotic common interacting promoter sites could be contained within the region upstream from the leader-coding sequence. In a search for such sequences, we have compared the DNA sequences upstream from the cap site for ovalbumin, rabbit β -globin (J. Van der Berg *et al.*; A. Efstratiadis, T. Maniatis and L. Lacy; personal communications), mouse β -globin major³⁴ and adenovirus-2 major late²² genes. When these sequences are aligned so as to emphasise sequence homologies as shown in Fig. 8, there is clearly a 7-base pair AT-rich region of approximate homology centred at about 28 base pairs from the initial nucleotide of the mRNAs. This region of homology, which may be a common interacting promoter site, is very similar to the 'Hogness box' which is of the form 5'-TATAAATA-3' (D. Hogness, personal communication) and has been found in an analogous location upstream from the startpoint of transcription of several genes including the histone genes³⁵⁻³⁷. No similar sequence exists in analogous positions upstream from the 5' end of any of the other ovalbumin exons (ref. 12, and our unpublished results). Note that, in all four cases compared, the AT-rich region of homology is flanked by GC-rich segments (Fig. 8), suggesting that the 'Hogness box' could be extended by three or four residues. There is some resemblance between this eukaryotic region of homology and the prokaryotic model sequence which has the Pribnow sequence at one end (Fig. 8), suggesting that prokaryotic and eukaryotic promoters could have some common features. However, the 'Hogness box' is in a position more closely resembling that of the prokaryotic recognition site than that of the Pribnow box. In this respect, it is interesting that the recognition site of the *E. coli lac* promoter centred at about -30 is bounded on both sides by GC-rich sequences³⁸.

There is a striking similarity between the 10 residues which precede the first nucleotide of adenovirus-2 late major and

Fig. 8 Comparison between DNA sequences of ovalbumin, rabbit β -globin, mouse β -globin major³⁴ and adenovirus-2 major late²² genes upstream from the 5' end of the mRNAs. The sequences are aligned to show their similarities. Numbering is in base pairs and negative numbers are given to nucleotides upstream from the 5' end of the mRNAs (position 1). The AT-rich region of homology is boxed with a continuous line. The GC-rich region of homology is boxed with a dashed line. Lines above or below the sequences delineate regions of partial two-fold rotational symmetry. Centres of symmetry are indicated by arrows. The prokaryotic promoter model sequence³² which has the Pribnow box at one end is given for comparison (the upper and lower case letters correspond to bases present at high and moderate frequency, respectively).

mouse β -globin major mRNAs, as previously noted by Ziff and Evans²². However, this homology does not extend to the other genes included in Fig. 8. Additional sequence data are required to decide whether there is a second, but weaker, region of homology with a location similar to that of the Pribnow box.

Regions of partial (hyphenated) two-fold symmetry are found around the probable start of transcription of the ovalbumin gene downstream from the possible RNA polymerase interacting site centred at about -28 (Fig. 8). Regions of hyphenated two-fold symmetry are also present in a similar location in the rabbit and mouse β -globin genes, but are absent in the case of adenovirus (Fig. 8). Elements of complete or partial two-fold rotational symmetry are found in prokaryotic operators and at other sites controlling prokaryotic transcription (refs 30, 32, 38-43). Further studies will reveal whether specific regulatory proteins, possibly related to the steroid hormone induction system, could bind to these symmetrical sequences which surround the probable ovalbumin transcription initiation site.

Biohazards associated with the experiments described here were examined previously by the French National Control Committee and carried out according to the rules followed by this Committee (le Progrès Scientifique, No. 191, Nov/Dec 1977). We thank Drs J. Dodgson, R. Axel, D. Engel and T. Maniatis for providing the chicken library used in this study; all those who sent us their results before publication, P. Kourilsky for discussions; C. Wasylyk, J. M. Garnier, M. C. Gesnel, E. Sittler, E. Taubert, A. Landmann and B. Boulay for technical assistance; A. Krust and M. Le Meur for ovalbumin mRNA, and P. Gerlinger for restriction enzymes. This work was supported by grants to P.C. from the INSERM (CRT 76.5.468 and 76.5.462), the CNRS (ATP 2117) and the Fondation pour la Recherche Médicale Française. J.P.L. and K.O'H. were supported by fellowships from the Université Louis Pasteur. A.R. is a postdoctoral fellow of the NCI of Canada.

GX339-4: a new black hole candidate

THE large area survey instrument on HEAO 1 has observed that the galactic X-ray source GX339-4 (4U1658-48) varies on time scales from tens of milliseconds to hundreds of days. Its long term variability was known from measurements made by OSO 7¹ and by Uhuru² but this is the first observation of aperiodic variability on time scales of tens of milliseconds to a few seconds. We show here that the overall characteristics of GX339-4 place it in the same class of X-ray sources as Cyg X-1 (ref. 3 summarises Cyg X-1) and Cir X-1^{2,4-6}.

The HEAO observations were made on 10-14 September 1977, 8-12 March 1978 and 10-14 September 1978. The average intensities in the 1-20 keV range of GX339-4 during these observations were ~ 0.25 , ~ 0.01 , and ~ 0.8 ct cm⁻² s⁻¹, respectively (1 HEAO ct cm⁻² s⁻¹ = 200 Uhuru flux units).

These values are approximate because the source was highly variable during the September 1977 observation, and because only a few quick-look observations were used to determine the March 1978 and September 1978 intensities. The first two intensities correspond to the 'low' and 'off' states defined by OSO 7¹. This is the first observation of detectable emission during the 'off' state. The third intensity falls between the 'low' and 'high' state values.

Detailed analysis has been made of ~ 200 s of data from the 'low' state observation in September 1977. GX339-4 was observed 20 times, ~ 10 s each, as the HEAO collimators ($1^\circ \times 4^\circ$ FWHM) scanned across the source. Fifteen of these scans were made with a time resolution of 320 ms and five were made with a resolution of 5 ms.

Figure 1 shows the intensity profile of GX339-4 observed with 320 ms resolution during three scans separated in time by 10 h and 18 h. The source intensities shown have been corrected

Fig. 1 Three scans through GX339-4 at 0.32 s resolution. Source intensities are plotted corrected for collimator response and with background subtracted. The background levels are shown for comparison.

Fig. 2 Three scans through GX339-4 plotted at a resolution of 40 ms. No corrections have been made to the rates. The dashed lines show the collimator's response.

for collimator response and the background has been subtracted. The background (cosmic diffuse X-ray and particle) was determined from measurements before and after the source passed through the field of view. Flaring activity with changes in intensity by factors of 3 on time scales of 0.32 to 1.28 s is evident. A study of the ~ 150 s of data from the source indicates that these flares occur at a rate of ~ 0.3 s $^{-1}$, have an average duration of ~ 1 s and contain about 15% of the power emitted by the source. The intensity of the source averaged over 10 s is variable of a factor of ~ 2 on 5-h time scales.

Figure 2 shows three scans through GX339-4 with a resolution of 40 ms. The rates have not been corrected for collimator response; the dashed lines show the expected response of the collimator to a non-varying source. Flares exhibiting intensity changes of a factor of ~ 3 with rise times from 40 ms to 160 ms are evident. Of particular interest is the series of five sequential flares occurring in the top scan with separations of ~ 250 ms (the separation between the peaks of the first and second flares is ~ 350 ms). This type of sporadic quasi-periodic behaviour is similar to episodes observed in Cyg X-1³ and Cir X-1⁶, and will require more detailed investigation to assess its significance.

The time scales of the variability of GX339-4 are displayed in Fig. 3. This figure was obtained by grouping 40 s of high-resolution data into non-overlapping segments covering 1.6 s, 0.8 s, 0.4 s and 0.05 s. For each of these segments a value of χ^2 was calculated using 10 resolution elements (durations of 160, 80, 40 and 5 ms, respectively) within each grouping. Plotted are the normalised number of segments with $\chi^2/9$ (nine degrees of freedom) greater than the value given by the abscissa. The total number of segments used range from 20 for the 160 ms grouping, to 800 for the 50 ms grouping. The calculated distribution for random data is shown for comparison. This analysis indicates that the source is not significantly variable on time scales between 5 and 50 ms, but is highly variable on longer time scales. HEAO 1 data from Cyg X-1 analysed in the same manner exhibit similar variability⁷. The true characterisation of the variability of GX339-4 will require a larger data base. Unfortunately, the source was in its 'off' state during a pointed observation with HEAO 1 performed on 2 October 1978. Data from a second pointed observation have not yet been analysed.

Fourier analysis of the limited data base failed to reveal any significant periodic power from 10 ms to 2.5 s. In contrast, an autocorrelation analysis of the data reveals significant correlation times from 0.3 to 0.6 s. This suggests that a shot noise model, similar to that used for Cyg X-1⁸, may be the best way to characterise its variability.

The temporal characteristics of GX339-4 resemble those of Cyg X-1^{3,7,8} and Cir X-1^{4,6}, two X-ray sources which are candidates for black holes in a binary system. These characteristics are summarised in Table 1. Much of the information in Table 1 is contained in ref. 9. Cir X-1 and Cyg X-1 are known to be binaries, whereas the data on GX339-4 are insufficient to reveal a binary nature. With the optical counterpart of GX339-4 now identified^{10,11}, this information may soon become available. All three sources have X-ray spectra which are harder during their low emission states. In a study of 43 galactic sources with Uhuru¹² only Cir X-1 and Cyg X-1 exhibited this extreme bimodal spectrum. Their soft-mode spectra are the second and third softest in the sample, the softest of all being GX339-4. However, GX339-4 did not exhibit striking variability in the Uhuru data. Cir X-1 and GX339-4 have what

Table 1 Characteristics of black hole candidates

	Cyg X-1	Cir X-1	GX339-4	V861 Sco OAO1653-40
1. Variability				
Orbital period	5.60 d	16.6 d	—	7.85 d
Bimodal X-ray spectrum	Yes	Yes	Yes	Unknown
Extended 'off' states	No	Yes	Yes	Unknown
Correlation time	0.5 s	Variable	0.3-0.6 s	Unknown
Shortest time scale	≥ 1 ms	≥ 1 ms	≥ 10 ms	Unknown
2. Optical companion/ emission lines	HD226868 O9.7 Iab $m_V = 8.9$	Faint highly reddened $m_R = 16$ strong H α and HeI emission	$m_V = 16.6$	HD152667 = V861 Sco B0.5 Ia H α emission
3. Mass function	0.22 $M_\odot$	—	—	0.487 $M_\odot$
M_1	$\geq 10 M_\odot$	—	—	7-11 $M_\odot$
4. Distance	~ 2.5 kpc	≥ 8 kpc ¹⁴	≥ 4 kpc	2 kpc ¹⁵
5. Maximum luminosity (erg s $^{-1}$)	$\sim 2 \times 10^{37}$	$\geq 10^{38}$	$\geq 2 \times 10^{37}$	1.5×10^{35}
6. Other emission	Radio, IR	Radio	—	UV

Fig. 3 The integral χ^2 distribution for corrected data sampled from GX339-4 on different time scales. The solid curve shows what is expected for random data. The numbers adjacent to the histograms give the range in time over which variability was tested (for example, the range 5-50 ms is indicated as 5/50). See text for details.

can be characterised as an 'off' state. We find that GX339-4 has an intensity of $\sim 0.01 \text{ ct cm}^{-2} \text{ s}^{-1}$ (~ 2 Uhuru flux units) while in this state. Cyg X-1 is not known to have a similar 'off' state. All three sources exhibit variability on time scales $< 100 \text{ ms}$.

Of the first three sources listed in Table 1, Cyg X-1 is the best black hole candidate. Its variable X-ray emission characterises it as a compact object. Furthermore, it is in a binary system for which both the orbital period and velocity are known³. From either the absence of eclipses or from photometric observations of the optical primary, it is possible to place a lower mass limit on the X-ray secondary. This is above the theoretical limit for neutron stars.

A complementary line of argument leading to a black hole interpretation of Cyg X-1 is derived from its variability over such a wide dynamic range of time scales, from milliseconds to years. No persistent periodic pattern has been observed; this is consistent with the central object being different from a pulsing neutron star. Other models have been suggested² but none seems more plausible than the black-hole model.

The case for regarding Cir X-1, and now GX339-4, as black holes rests on the similarity of their X-ray emission to that of Cyg X-1. They exhibit a similar range of time scales, essentially the same luminosity, and the same bi-modal spectral behaviour.

Table 1 includes the characteristics of V861 Sco which has been recently identified as an X-ray source¹³. The large mass of the non-optical companion and its compact nature, as inferred from the X-ray eclipses when it is occulted by the primary star, are strong evidence in favour of its identification as a black hole. Its luminosity is a factor of 100 less than the other candidates listed. This may be indicative of a fundamental difference in their natures. The determination of the characteristics of the variability of V861 Sco awaits future higher sensitivity studies in progress by satellites such as HEAO and SAS 3.

Semi-periodic pulsations in circinus X-1

CIRCINUS X-1 (4U1516-56) was first detected in 1969 (ref. 1) and has since been studied in X-ray, radio, and optical wavelengths. Particular interest in this source has resulted from its resemblance to Cygnus X-1—a suspected black hole. Both objects have X-ray luminosities in the range 10^{37} – $10^{38} \text{ erg s}^{-1}$ (refs 2,3). Both exhibit rapid intensity variations with timescales as low as 1 ms (refs 4,5), and as long as seconds or days⁶⁻⁸. Both X-ray sources are in binary systems; the orbital period reported for Cir X-1 is 16.585 d (ref. 9). Cir X-1 differs from Cyg X-1 in that the total mass of the binary pair is unknown. While an optical candidate has been found¹⁰, no estimation of its mass has been made, so that the evidence for its being a black hole is not as strong for Cir X-1. Variable IR emission¹¹ has been reported from the companion. There have been conflicting reports of X-ray periods of the order of seconds: Margon *et al.* suspected a period of 0.685 s and Toor reported a possible 2.2 s period⁴. We report here our investigations, using HEAO A-1, of these semi-periodic pulsations in Cir X-1.

The main portion of the HEAO A-1 experiment consists of four large-area xenon-methane counters with a combined area of 6,800 cm^2 and an effective energy range of 0.5–25 keV. The counters have a $1^\circ \times 4^\circ$ collimator. The roll of the HEAO A-1 causes a point source to be scanned by these modules in 10 s, and a source remains in view for approximately 8 d. The scan modules are on the -y side of the spacecraft. On the opposite side is module 7, which has 1,900 cm^2 effective area. Its collimator, which is $8^\circ \times 2^\circ$, has the longer direction aligned with the scan, so that a source remains in view for about 80 s. Timing resolution is normally 320 ms for all modules, but 5 ms resolution is available.

Before 0200 UT on 28 August 1977, the observed intensity of Cir X-1 was low. At that time, there was a dramatic increase and the source continued in a high state for two more days, after which it left the field of view. Throughout this time the average intensity varied by as much as a factor of 2 during the 15–30-min intervals between successive scans.

Fig. 1 A scan through Cir X-1 with module 7 using 640-ms sums. The triangular response of the collimators is represented by the two straight lines. A steady source output should follow these lines, but regularly spaced pulses appeared instead. The spacing seemed to be 2.5 s (there are 10 pulses in 39 bins, that is, the period is 2.50 ± 0.06 s).

The data base accumulated during the high state consists of 77 scans with modules 1-4, and eight good scans with module 7. Five of the scans with modules 1-4 used 5-ms timing resolution, but all of the module 7 scans had 320-ms timing resolution. The total observing time from all scans is 20 min.

Erratic intensity variations were observed on all scans, and on many scans no pattern in the variability was evident. A notable exception was the pass shown in Fig. 1, where a train of pulses lasting for 40 s was seen by module 7. The time between successive pulses was 2.5 s. On several scans, modules 1-4 observed similar pulsing. Figure 2 shows two scans, one with the pulsing and one without.

Although not all scans showed periodic pulsations, the pattern on the scan shown in Fig. 1 was sufficiently distinct (with individual pulses standing out at 5σ) for a more systematic search for periodicity to be undertaken.

In this search, four hypotheses were considered: (1) the pulsing in Fig. 1 was of instrumental origin; (2) Cir X-1 varies periodically with a 2.5 s period; (3) the source is not strictly periodic, but has some quasi-periodicity, such as a characteristic recovery interval following each burst or perhaps a periodic component which is sometimes clearly present and other times absent or masked by aperiodic variability; and (4) the intensity variations are aperiodic, that is, burst times are completely random (shot noise).

To test the third conjecture required high sensitivity, so that individual bursts could be isolated and their times could be determined.

Module 7 has intermittently exhibited a high, irregular count rate, thought to be due to electrical noise. At other times it responds normally to sources and has a low background rate. We have devised four data acceptance criteria: first, the count rate before and after a source must reach the normal background level; second, the count rate before and after a source must follow Poisson statistics; third, response to nearby constant sources must follow the known collimator response function; and finally response to Cir X-1 must not extend beyond the full width of the collimator. Eight scans of Cir X-1 on module 7 fulfilled these criteria. As we do not fully understand the nature of the malfunction, it is still possible that the periodicity in Fig. 2 is an instrumental effect. It should be kept in mind that scans from modules 1-4, which are free of this problem, show the same quasi-periodic pulses (Fig. 2).

The search for periodic pulsations was conducted using three methods. (1) Fourier analysis. Each of the scans from module 7 was Fourier analysed. Only one showed a significant peak at 2.5 s. The expectation value for this peak was 1 in 220. (To check for systematic effects, module 7 data at different times was Fourier analysed and no significant peak at 2.5 s was found). Scans from modules 1-4 were not Fourier analysed, there being only 32 points per scan, against 320 in module 7. (2) Epoch folding. The epoch-folding technique is more sensitive than Fourier analysis and can be used when the period is approximately known. Again, only the single pass from module 7 showed a significant peak. (3) Epoch folding of multiple passes. Data can be epoch folded from several scans of the source by inserting strings of zeros to fill the half-hour intervals between scans. A certain assumption needs to be made about unknown orbital parameters of the binary system which was that these effects were negligible. A search for periods near 2.5 s with this method failed to find a significant periodicity.

A comparative test of the hypotheses of quasi-periodicity and random bursting was made using the distribution of intervals between successive bursts. A rise in count was called a burst only if it stood out by at least 2σ above immediately adjacent data, that is, when there was a bin with high count which was both preceded and followed by bins with a count at least 2σ lower. The time of the burst was identified with the local maximum, and the inter-burst interval was the difference in time between two successive bursts. Figure 3 shows the distribution of such intervals.

If the bursts are randomly distributed in time, the distribution of intervals will be exponential, with a characteristic time which is the inverse of the mean rate. The circles show the distribution

Fig. 2 Two consecutive scans from module 1-4 (corrected for collimator response). On the left one can see a train of three 2.5-s pulses; on the right, the normal erratic behaviour of Cir X-1.

expected if we fit the characteristic interval to the observed rate of bursting. There is a large excess in the number of intervals falling near 8 bins, or 2.5 s. The χ^2 value for the observed distribution is 57, giving a probability of 10^{-5} . The poor fit is due primarily to the contribution from intervals near 2.5 s. We therefore conclude that 2.5-s intervals from Cir X-1, as measured by modules 7 and 1-4, are more frequent than expected for randomly distributed events.

A random distribution of burst times fails to provide a good fit to the distribution of intervals between bursts, because there are many intervals near 2.5 s. Although this suggests a periodicity,

Fig. 3 The histogram shows the distribution of intervals between successive bursts seen in modules 1-4 and module 7. Circles represent the values that would be expected for a shot noise model.

and although highly periodic behaviour is seen on one scan, strict periodicity does not fit the observed intensity variations.

An alternative interpretation is that there is a characteristic delay following one burst before another can occur, and that in short data samples this sometimes gives the appearance of periodicity. This would mean that times of burst events are not completely independent, as in the shot noise picture.

Structure of lithium-sodium β -alumina by powder neutron diffraction

THE first structural determination of a β -alumina compound containing two different alkali ions, lithium and sodium, in crystallographically distinct sites in the conducting plane is reported here. The lithium ions are displaced by about 1 Å from the mirror planes. Although such a displacement has been suspected it has not hitherto been confirmed.

Polycrystalline lithium-sodium β -alumina, with the two alkali species present in roughly equal proportions, has been shown to be a very good conductor of lithium ions¹. Although definitive

single crystal measurements have not been reported, the conductivity at room temperature, as measured by multi-frequency analysis of polycrystalline samples, is over 10^{-3} S cm⁻¹, the highest reported for any Li⁺ ion conductor. The ionic current is carried almost exclusively by lithium. The thermodynamic equilibrium is such that exchange of lithium for sodium above ~50–60% is difficult to achieve, and the ionic conductivity decreases if this is done. Such behaviour is in distinct contrast to the mixed alkali effect recently described² in sodium-potassium β -gallia, where, as in mixed alkali glasses, the ionic conductivity drops below that of either of the end members. This difference could arise if the structural distinction of the two alkali species, which we demonstrate in lithium-sodium β -alumina, is not a feature of most mixed alkali β -aluminas.

The structure of sodium β -alumina was determined in 1971 (ref. 3) and sodium atoms are found near the Beevers-Ross (BR) and mid-oxygen (MO) positions (Fig. 1). The structure of lithium β -alumina has not been reported, but the positive pressure coefficient of resistivity⁴ can be interpreted as indicating a displacement of lithium off the mirror plane at atmospheric pressure. Such a displacement would be expected from the known positions of the spinel block oxygen atoms and the effective ionic radii of lithium and oxygen⁵. When lithium is incorporated by ion exchange, as in the present work, it is expected to be present in the conducting plane. If incorporated during sintering and sample preparation, lithium will stabilise the β' phase⁶ and is then presumably present in the spinel block, although this has not been demonstrated by structure analysis.

Table 1 Lithium-sodium β -alumina, PANDA diffractometer, $\lambda = 1.534$ Å (atom positions at 4.2 K)

Atom	Position	x/a	z/c	B (Å ²)	Occupation
O(1)	12k	0.15655(40)	0.04957(12)	0.14(5)	6
O(2)	12k	0.50220(48)	0.14682(11)	0.33(6)	6

Al(2)	4f	1/3	0.02430(45)	0.55(15)	2
Al(3)	4f	1/3	0.17575(48)	0.83(17)	2
Al(4)	2a	0	0	0.46(22)	1
Li	6h	0.834(17)	(0.2086(34)	1.0	0.57(11)
Na	6h	0.7182(41)	1/4	1.0	0.44(5)

Cell parameters: $a = 5.5923(4)$; $c = 22.5576(6)$.

Data were collected on the PANDA diffractometer, Harwell ($\lambda = 1.534$ Å). The starting material was Monofrax sodium β -alumina containing 6.4% Na₂O (1.24 Na₂O : 11 Al₂O₃) which had been 60% exchanged with lithium in molten lithium nitrate. It was maintained at liquid helium temperature to minimise thermal motion effects which are difficult to distinguish from atomic displacements at higher temperatures in materials such as the β -aluminas, where several sites in the mirror plane may be partially occupied by the same atom. The data were refined using the profile refinement method described by Rietveld⁷.

The final atomic positions and thermal parameters are given in Table 1. The weighted profile agreement factor was 0.069. The accuracy obtainable using the powder technique does not allow a very precise determination of the occupations of the alkali ions, but the occupation numbers determined are close to those expected from the chemical composition (0.74 Li, 0.50 Na). The temperature factors of both atoms were constrained at 1.0 Å². Nor can we determine unequivocally by powder diffraction the structural basis of the observed non-stoichiometry in β -aluminas. The refinement in Table 1 assumes a

Fig. 1 The β -alumina structure. One half of the unit cell is shown in (a). A projection of the conducting plane is shown in (b) with the Beavers-Ross (BR), mid-oxygen (MO) and anti-Beavers-Ross (ABR) sites labelled. The directions of the small displacements often observed are indicated. For the sodium atom at the BR position in lithium-sodium β -alumina, there are three equivalent possible directions of displacement

stoichiometric spinel block. However, incorporation of 0.24 interstitial aluminium displaced from Al(1) sites, and 0.12 oxygen atoms in the mirror plane close to the mid-oxygen sites in accord with the observed non-stoichiometry, causes a small increase in the lithium occupation to 0.65(12). The sodium occupation (0.47(5)) is virtually unchanged as are all other parameters. Both alkali occupations are then within one standard deviation of the expected values. This model of defect compensation, first suggested by Roth *et al.*⁸ for sodium β -alumina, and found for potassium β -alumina by Collin *et al.*⁹ seems, therefore, to be applicable in the present compound.

The relatively weak scattering powers of lithium and sodium for neutrons entail only a weak (1%) dependence of the R -factor on their presence. We believe, nonetheless, that the results obtained are meaningful, both because of the concordance of the occupations and positions with expectation, and because satisfactory refinements were not obtained with the alkali ions in alternative locations in the conducting plane.

The important structural conclusions about lithium-sodium β -alumina which may be drawn from the present work are then that the lithium and sodium are localised on crystallographically distinct sites and that lithium is displaced off the mirror plane. The sodium location, about 0.5 Å from the BR site, is very close to the dominant sodium location observed in sodium β -alumina³. Na-O(2) distances are 2.722(7) and 3.130(8) Å. The nearest Na-O(5) distance is 2.805(11) Å.

Lithium is displaced ~1 Å off the mirror plane and is located almost exactly over the MO site. Li-O(2) and Li-O(4) distances are 2.126(52) and 2.198(71) Å respectively. This displacement is necessary to reduce the Li-O distance to a value close to the sum of the ionic radii ($O^{2-} + Li(IV) = 1.99$ Å (ref. 5)).

Although we have shown the first structural distinction of two different alkali ions in the conducting plane of β -alumina, a structural determination on its own cannot explain the observed conductivity data¹. Long conduction paths are probably present for lithium motion without blocking by static sodium atoms; the role of the β -alumina framework and the sodium ions in promoting lithium ion mobility might be revealed by lattice statics or molecular dynamics calculation. The observed Li-O

distance, and, particularly, the minimum ABR-O(4) distance (2.43 Å), are all greater than the sum of the ionic radii. Therefore, we still need to know the optimum size of hole or slot to expedite rapid Li^+ motion, if indeed such a parameter can be defined without reference to a particular structure type.

Interconnected fibre masses precipitated from solutions of polymers

IN studies to increase the mechanical strength of polymeric encapsulants for high voltage electronic devices we have formed fibre masses of unusual structure from isotactic polypropylene. The method for producing these three-dimensionally interconnected fibrous structures is described here and involves agitation of a solution of the polymer at sonic frequencies with simultaneous cooling. This process has since been observed for polyethylene and polybutene-1. Furthermore, the process has

Fig. 1 Schematic diagram of experimental apparatus for low frequency agitation of polymer solutions.

been extended to other polymers, both crystalline and non-crystalline, through a process we call 'seeding'. Uniform reinforcement of encapsulating resins through the addition of high strength, short fibres, is not practical because of the complex shapes and numerous small interstices of the devices to be encapsulated. We therefore set out in 1973 to form fibres *in situ* by precipitation from low viscosity solutions which would readily impregnate a device of complex geometry. As a secondary objective, we hoped to polymerise the solvent to form a matrix around the fibres thereby producing a self-reinforced composite.

The fibrous crystal form of polymers was first reported in 1959 (ref. 1). This new crystal geometry, which consists of folded chain platelets regularly spaced on a central core of highly aligned polymer molecules, has been termed the 'shish kebab' structure. Pennings^{2,3} and Wikjord and St John Manley⁴ reported the formation of fibrous precipitates, almost entirely of the shish kebab structure, on the stirrer by stirring supercooled solutions of polyethylene and isotactic polystyrene respectively. Fibres have also been prepared by vigorous stirring of isotactic polypropylene, polyoxymethylene and polyethyleneoxide. Although the formation of high strength fibres by the creation of a sustained, essentially unidirectional, velocity gradient in a solution by stirring, high velocity jet, and other mechanical devices has become commonplace, there has been only one report of the use of high frequency agitation. Blackadder and Schleinitz⁵ found that irradiation of a dilute solution of polyethylene in *p*-xylene with ultrasonics from 85 to 190 kHz between 82 and 88 °C caused the formation of small fibrous crystals consisting entirely of the shish kebab structure.

Pennings⁶, in his study of the mechanics of fibrillar crystal growth, concluded that the creation of velocity gradients within the solution is the primary requirement. Extending this conclusion to the formation of fibre masses, we hypothesise that velocity gradients are generated in the solution by the sonic agitation. The hydrodynamic forces imposed on the coiled molecules by these velocity gradients cause them to extend completely or partially. Assuming that the thermodynamic conditions are suitable, the extended polymer chains and segments of chains have the opportunity to crystallise with each other in a substantially parallel or orientated manner. Segments of polymer coils which extend into the streaming solution, also undergo extension and orientation, thereby accelerating the growth process, and forming new branches of the original fibres. On cessation of the perturbing hydrodynamic forces, the segments of polymer chains extending from the partially orientated core of the fibre tend to crystallise in the usual folded chain configuration. They may account for the spherulitic and shish kebab-like structures which are often found mixed with the fibres.

In our initial experiments, we found that the stirring technique was an excellent way of establishing optimum conditions, such as

type of solvent, polymer concentration and temperature, for fibre deposition. Stirring, however, causes fibres to form on and extend from only the exterior surface of the rotating member and therefore was not suitable for forming fibres in and around complex shapes. Ultrasonic formation of fibres was ineffective; the yield of fibres was sparse and the fibres were discrete and very short. We then decided to try the effect of agitation at sonic frequencies on relatively concentrated polymer solutions. The apparatus used for these experiments is shown in Fig. 1. We placed a test tube of hot polypropylene solution in the sample holder and subjected it to low frequency agitation as it cooled. At a few degrees below the dissolution temperature dense fibre masses began to form in the solution. These masses grew until they filled the entire fluid volume of the container. The fibre masses were usually so densely interconnected that they had good mechanical integrity and retained the entire volume of the solvent.

Isotactic polypropylene proved to be most amenable to the formation of fibrous masses. Concentrations of 0.7–20% polypropylene were dissolved in *p*-xylene at 132 °C and allowed to cool while the frequency of vibration was scanned in the 80–1,000 Hz range. Dense fibrous mats were formed. In other experiments, fibre masses were formed from concentrations of 5% and 10% isotactic polypropylene in styrene monomer inhibited with 0.5% hydroquinone. The styrene-impregnated fibre plugs were then placed in an oven at 70 °C to polymerise to monomer into a plastic matrix of polystyrene to form a self-reinforced composite.

Fig. 2 Polypropylene fibre mass showing branching and interconnection. Scanning electron micrograph ($\times 4,800$).

Interconnected fibrous masses have been formed from polyethylene, isotactic polybutene-1 and isotactic poly-4-methylpentene-1. Polypropylene has also been used to induce other linear polymers, including Nylon 6, acrylonitrile butadiene styrene terpolymer, polystyrene, polyvinylidene fluoride, and tetrafluoroethylene hexafluoropropylene vinylidene fluoride terpolymer, to co-deposit in fibrous masses. This is the technique which we have called seeding. It is possible that the phenomenon of fibre mass formation under sonic agitation is general for isotactic crystalline polymers provided the optimum solvent system, concentration range and precipitation temperature is selected. Furthermore, the technique can be extended by seeding to many other linear polymers.

Fig. 3 Fibrillar structure of fibres from fibre mass scanning electron micrograph ($\times 11,000$).

The morphology of the fibrous masses depends on many factors including concentration, rate of cooling, solvent type and the frequency and effectiveness of the agitation. In general, the most uniform, highly orientated, fibrous and highest strength fibre masses are produced from fairly low concentrations at very slow rates of cooling during precipitation. The precise mechanism of fibre mass formation by sonic agitation is not understood. We do not know whether the hydrodynamic shearing forces necessary for initial fibre formation are produced by cavitation, interaction of the solution with the walls of the container or some combination of perturbations. The following general observations may be helpful. Isotactic polypropylene very readily forms fibre masses from several solvents such as *p*-xylene, styrene, toluene, and mixtures of styrene, acrylic acid and methylmethacrylate. Lower viscosity solutions form fibres more readily than viscous, concentrated solutions. Efficient coupling between the container of the polymer solution and the shaker is important for the formation of uniform fibre masses. Frequency of agitation in the sonic range does not seem to be important except that those frequencies which are resonant with the container of polymer solution will cause the most efficient agitation and result in the most uniform fibrous masses. Also, a small air-filled space between the cap of the container and the surface of the solution seems to be necessary. Fibre plugs will not form in a full test tube which is sealed with an impervious rubber stopper but will form when the rubber stopper is replaced with a cork.

The structure of a well formed fibrous mass is shown in Fig. 2. If the solution is cooled too rapidly, or is too concentrated, the fibres will be co-deposited with spherulites and flocculent material. The fibres vary from 300 Å to about 0.3 mm in diameter and are variously branched or bifurcated to form an interconnected, three-dimensional network. Examination of the fibres at high magnification reveals that they seem to be made up of essentially parallel arrays of fibrils (Fig. 3).

We and our co-workers have subsequently formed fibre masses by a variation of the sonic agitation technique which permits more precise control of the experimental conditions. Fibres from these experiments have the shish kebab morphology and greatly improved strength over the bulk polymers. This work will be reported elsewhere.

This study was supported as a Hughes Aircraft Company Independent Research and Development Program and has

resulted in the filing of several patent applications to cover fibre masses and the 'seeding' technique. We thank C. G. Walance and G. R. Hokenstad for their support and R. E. Kelchner for his technical advice.

Sea-level changes during the late Pleistocene and Holocene in the Strait of Malacca

CURRENT concepts of late Pleistocene sea level history, generally referred to the ^{14}C time scale, differ considerably¹. Some authors^{2,3} assume that the sea level at about 30,000 BP was comparable with that of the present and others^{4,5} assume a considerably lower sea level at that time. We have now obtained ^{14}C dates from *in situ* roots and peat which indicate that the sea level was lowered eustatically to at least 40–60 m below the present level between 36,000 and 10,000 BP. The sea level rose from –13 m to about +5 m from 8,000 to 4,000 BP and then approached its present level.

A combined coastal and offshore survey in the Strait of Malacca between Port Dickson and Singapore yielded 33 reliable ^{14}C ages obtained from autochthonous organic material such as peat and roots (Table 1). In the coastal region, samples were collected by hand augers which could penetrate up to 18 m of unconsolidated sediments. In the offshore area a shipboard-operated vibrocorer was used which recovered cores up to 3 m long. Samples were obtained between 75 m below and 6 m above mean sea level.

The geological settings of the dated layers cannot all be used as direct indicators of sea level but can serve as indirect indicators. In the offshore zone, the substratum of the peats is mostly unknown, because the vibrocorer did not penetrate the peat layers. Some of these peats may have been formed in association with freshwater lakes, as indicated by the presence of a diatom ooze. The upper parts of the peat and their possible sedimentary cover were eroded during the Holocene transgression or by sub-Recent tidal currents. Today the peats, which have a fresh and unweathered appearance, are mostly overlain by sandy marine sediments. Data obtained from this type of peat indicate only that the sea was below the sampled level during the time of peat formation. The same conclusion can be drawn from *in situ* roots in terrestrial sediments.

The Holocene basal peats of the coastal sedimentary sequences were formed on top of terrestrial deposits usually with no erosional hiatus between them and the overlying marine sediments. In this case it can be assumed that the sea invaded the area shortly after the phase of peat formation.

In wide areas of the coastal lowlands, peat occurs as an organic cover on the top of clastic deposits. This overlap of a semi-terrestrial facies over brackish and marine facies indicates the beginning of regressive tendencies in the coastal development. Mangroves are direct indicators of the tidal zone between mean neaps high and mean springs high (at present ~1.3 m).

Depth distribution of ^{14}C ages of autochthonous organic material of the sampled core sections (Figs 1, 2) shows that

Table 1 ^{14}C dates from *in situ* roots and peat

between approximately 40,000 and 10,000 BP continental conditions prevailed in most parts of the southern Malacca Strait. Between 40,000 and 38,000 BP peat was formed at 17 m below present sea level, and around 34,000 BP at -67 m. Leaves and wood found at -36 m in freshwater diatom oozes gave ^{14}C ages of 32,800 and 26,300 BP. *In situ* roots, presumably from a former mangrove swamp at -65 m and with a ^{14}C age of 27,400 BP, give the only direct time-depth position of a Pleistocene sea level. *In situ* roots from terrestrial sediments and peat grew at -55 m between 23,800 and 17,200 BP. Three additional peat dates from the Strait of Malacca^{6,7} and the southern Gulf of Siam⁸ supplement these dates. From 8,000 to 6,000 BP the sea level rose from -12.8 m to +1.2 m relative to the present level.

Sea level indicators for the time interval between 5,000 and 4,000 BP have been found at +2.5 m to +5.8 m, which is the highest dated level. The subsequent lowering of the sea level to its present value is indicated by a peat sample at +2.0 m with a ^{14}C age of 2,000 BP and two mangrove samples at -0.8 m, dated at 1,000 BP. This tendency is consistent with the results of Tjia *et al.*⁹. However, our data do not show whether the lowering of the sea level took place steadily or through an oscillatory process.

The reliability of conclusions concerning sea level history is limited by the errors involved in ^{14}C dating, and in correlating

the sample sites with the corresponding sea levels. For the dating of our offshore peat samples, only contamination by younger roots need be taken into account. Because of the fresh appearance of the peats and their stratigraphical position below the marked marine erosional horizon, such roots were not expected and they were not found. These roots would also have to be older than 10,000 yr because of the Holocene transgression, and in our experience contamination by finely dispersed macroscopically invisible roots is generally lower than 3%. With the most unfavourable of these assumptions, samples with actual ages of 100,000, 40,000, 30,000, and 20,000 yr would correspond to ^{14}C ages of 38,000, 33,600, 27,700 and 19,500 yr, respectively. In other words, the ^{14}C time scale seems to be increasingly compressed towards the earlier end of the scale.

The amount of compaction which may have changed the depths of the sea level indicators is unknown for the offshore area. For the coastal area it can be estimated roughly to be up to 5.5 m. This is the height difference between the highest sea level indicator in the sedimentary sequences and the corresponding level of a marine abrasional platform on weathered granite.

The curve for Holocene sea level changes in the Strait of Malacca compares well with those areas which are considered to

Fig. 1 Depths and ^{14}C ages of sea level indicators. The dotted line shows the change of the sea level for the past 10,000 yr (see also Fig. 2).

be tectonically stable, like Mauretania¹⁰ and Mozambique¹¹. This similarity indicates that at least during the Holocene the Malacca Strait area was not influenced by tectonic subsidence or uplift. These conditions seem to have prevailed over a longer period. From the palaeogeographical pattern of marine Tertiary sediments¹², it is obvious that the Malaysian Peninsula was either terrestrial or has been uplifted since that time.

Because secondary effects such as compaction and tectonic subsidence as well as contamination affected our data on the original depth and age very little, the formation of Pleistocene peat and mangroves at the bottom of the present Malacca Strait are explained by eustatic lowering of the sea level. Although the Pleistocene dates are not suitable for construction of a sea level curve, they support the conclusion that the sea level was lowered worldwide by at least 40–60 m from 36,000 to 10,000 BP.

Our conclusions are supported by a date from the shelf off the Ivory Coast¹³, where peat at –65 m indicates continental conditions at about 23,000 BP. The unpublished date of $36,150 \pm 3,000$ BP (Hv 6280) from a humous sand taken at –38 m from the shelf of northern Mozambique also corresponds to continental conditions. ^{14}C and $^{230}\text{Th}/^{234}\text{U}$ dates from New Guinea also indicate a –40 m level at 30,000 and 40,000 BP¹⁷.

In contrast, the often-reproduced sea level curves from Curray² and Milliman and Emery³ show a high sea level for around 30,000 BP, levels that are comparable to the present level. The discrepancy between their results and ours is surely due mainly to their use of mobile carbonate material such as shells, ooids, and pieces of carbonate cemented sand, which would result in dubious ^{14}C ages and erroneous sea level indications. This material could have been reworked¹⁴ or rejuvenated by contamination during several thousand years of sub-aerial weathering¹⁵. Consequently, the ^{14}C time scale used by Curray² and

by Milliman and Emery³ seems much more compressed at the earlier end of the scale than ours. Accordingly, the high sea level postulated by these authors most probably belongs to an older warm period, presumably to the last interglacial period. Our interpretation agrees well with the sea level reconstructions based on global climatic history^{4,5} and the changes in the oxygen isotope ratio in deep-sea sediment cores¹⁶, which assume low sea levels for the period around 30,000 BP.

Fig. 2 Sea level curve for the past 7,900 yr.

Maximum density of random placing of membrane particles

THE apparently simple problems of (1) how many short lines ('cars') of the same length can be randomly placed ('parked') in non-overlapping fashion on a line ('street'); (2) how many squares (Fig. 1) or disks (Fig. 2) of the same size can be randomly placed in an area without overlapping; (3) how many solid spheres (atoms) can be randomly packed in a given volume, are of interest from both physical and mathematical points of view, and occur in various situations¹. Our interest in the two-dimensional problem arises from a computer simulation^{2,3} of particles

Table 1 The maximum fraction f of an area covered by randomly placed particles

Square particles		Method, coarse mesh (except as indicated)

Mean 0.5027. Standard deviation 0.0033.

cell membranes. When the membrane bilayer is split into two leaflets by freeze-fracture method⁴ and an area of the split membrane is visualised by electron microscopy, then the imbedded membrane particles (believed to be predominantly roteineaceous) are seen as circular shapes. In natural membranes the unaggregated particles seem to be random in position, and the areal density of the particles may be high. It seems that nature has provided us with a two-dimensional sample of (nearly) maximum random parking. Hence we have estimated the maximum fractional area covered by circular disks in a two-dimensional membrane, using a computer simulation with periodic boundary conditions. The correspondence with articles in a biological membrane has implications for membrane biogenesis.

The two-dimensional random sequential placing ('car parking') problem may be described as follows. Cars, each of the same size, are dropped from the air one at a time into the empty space of a parking lot. The place to park each car is chosen so that there is a (uniform) probability of parking on the remaining empty space. When no more cars can be parked (without overlapping one another) then the parking lot is 'saturated', and the fractional area f of the lot which is occupied by cars is the quantity of interest. Palásti⁵ conjectured from the one-dimensional case that in two dimensions $f \sim 0.5589$. Previous simulations of the two-dimensional case^{1,5-7} have taken the cars to be square, with sides always parallel to those of a square parking lot of finite extent ('rigid boundary'). Here, Monte Carlo analogues are used to find f for circles and for squares, with periodic boundary conditions being novel in the present context. The choice of computing technique is most important, as it is affected by the expense of computation time.

We used two basic methods for placing particles by computer: (1) the coarse-mesh method for square particles only; and (2) the fine-mesh method for square and disk particles. They will be described in detail elsewhere³.

Method (1) is an improvement of that of Akeda and Hori^{6,7}. Some results are shown in Table 1. The principle of the fine-mesh method is that the parking lot is covered by a fine mesh of squares which are much smaller than a particle: a particle (disk) is centred on a square, and the particle is then represented by the minimum set of fine squares which will completely cover the area of the particle. To obtain reasonable accuracy (to three significant figures in placement) the square 'parking lot' was divided into a mesh of 1024 × 1024 fine squares: the

availability status (whether or not a fine square was available for a particle centre) was stored as a bit in a single megabit array. Square particles (used for checking the fine-mesh method against the large-mesh method) were $(65/2) \times (65/2)$ fine squares in size; circular particles were of diameter 55/2 fine squares.

The essence of the fine-mesh method is that, by careful counting, the problem of making many trials to avoid overlaps is eliminated, which is unavoidable in the large-mesh method. As the centre location for each particle is randomly selected directly from those fine meshes available, then the neighbouring region thereby excluded to another particle is also determined and recorded in the megabit array: this region will be a square of 65×65 or a circle of diameter 55 fine meshes. The areal error due to representing the smooth outline of a circle by an outline made from many small squares is much less than 1.5%.

To identify directly the next vacant fine squares on which a particle centre might be randomly placed, two additional 1,024 long integer arrays are used (that is, two integers for each row of the 1,024 × 1,024 array) for the book-keeping purposes.

Fig. 1 Sample of large mesh method for randomly sequentially placing square particles into a square region.

To produce plots such as Fig. 2, an integer array is used to record the coordinates of the particle centres. To reduce the particle placement time, the shape of one-quarter of a particle is stored in an integer array (further details required to make the method feasible are given in ref. 3).

A great advantage of the method is that the computer time required to find a location for each particle is the same for each placement (parking). Particles are placed until there is no space available for a particle centre. While the time required to place a particle is quite long (48 ms to place each $(65/2) \times (65/2)$ square particle, including all book-keeping, on IBM 370/168), it remains independent of the number of particles placed. (The time and memory requirements of the program increase drastically with the accuracy of the placement desired. To add one

Fig. 2 Sample of fine mesh method for randomly sequentially placing circular particles (disks) into a square region. (The area shown is covered by a square mesh—not shown—of $1,024 \times 1,024$. Also, the disks have been synthetically shadowed so as to simulate the appearance of freeze-fractured particles, which usually seem to be hemispherical.)

significant figure of accuracy in the two dimensions would increase both the time and memory requirements of the computer program 100-fold.)

The new result for the fractional area covered by maximally packed disks is 0.5027 ± 0.0020 . We are not aware of any theoretical (or previous experimental) estimate (and simply note that this result is not inconsistent with the difference in shape between circles and squares, and that the squares were all orientated with sides parallel). For the maximum fractional area f covered by non-overlapping orientated square particles on a surface, in addition to Palásti's⁵ conjecture of 0.5589 and Akeda and Hori's⁷ extrapolation of a simulation with rigid boundary conditions of 0.5626 ± 0.0006 , we now have simulations with more realistic periodic boundary conditions which do not require extrapolation. These new results are for the coarse-mesh method $f = 0.5629 \pm 0.0016$ (lower bound) and $f = 0.5649 \pm 0.0016$ (upper bound) (errors are 95% confidence limits about the estimated mean), and for the fine-mesh method $f = 0.5538 \pm 0.0035$. (The nominally low error quoted⁶ is statistical, due to taking many samples, and will not affect the methodological problem associated with rigid boundaries in their simulation.) These new results bridge Palásti's conjecture⁵. Hence, in contradiction to other simulations⁷ these new results together show that simulations give no reason to reject her⁵ conjecture for orientated squares.

The areal density of particles in the human erythrocyte membrane² is substantially close to that of the maximum placing

of disks. As during membrane biogenesis^{8,9} proteins may be inserted into the membrane in a sequential process, it seems that to avoid the time and energy costs of many insertion attempts, the membrane must permit the protein to move laterally after insertion, that is, there must be at least short-range membrane fluidity⁹.

The greening of polar bears in zoos

POLAR BEARS (*Thalarctos maritimus*) normally have creamy-white fur, presumably an adaptation for camouflage in a snowy environment. However, during the summer of 1978, the fur on the back and sides of three adults in the San Diego Zoo turned green, though the animals remained otherwise healthy. (Of these bears, one female was born in the zoo in Calgary, Alberta, Canada, in 1966 and was transferred to the San Diego Zoo in 1969; a second female was born in the wild, having been caught at Spitzbergen in 1951; the third, a male, was born in the San Diego Zoo in 1970.) This phenomenon, though less marked, has been noted in several previous summers, both here and in zoos elsewhere, for example, in Cologne, Germany (C. Hill, personal communication). The coloration was particularly evident on the flanks, on the outer fur of the legs and in a band across the rump: fur on the head and belly and inner sides of the legs was white. We first supposed that the colour was due to green algae such as *Chlorella* or *Scenedesmus* on the surfaces of hairs, growth of such algae being promoted by the presence of nitrogenous wastes in the waters of the bears' pool. (The pool in the exhibit area, which contains 12,500 gallons of tap water, is drained and cleaned twice weekly.) However, microscopic examination of samples of hair taken from the three San Diego bears and from a similarly green polar bear in the zoo at Fresno, California, revealed that this was not so. The outer surfaces of the hairs appeared clean and smooth, except for the normal squamation. The coloration was clearly attributable to the presence of algae inside the hairs, specifically in the hollow medullae of many of the wider (50–200 μm), stiffer guard hairs of the outer coat. (The thinner (<20 μm) and more undulant hairs of the under coat, which were not hollow, were colourless.) Some of the lumina were apparently filled with air, but many of these hollow spaces were partly occupied by masses of small greenish cells, which we describe here.

Fig. 1 *a*, Portion of green polar-bear hair, showing medulla containing air cavities and sections filled with algal cells. Note lateral ducts. *b*, Broken end of green polar-bear hair, showing medulla containing algal cells. *c*, Portion of green polar-bear hair, showing medulla with numerous lateral ducts. *d*, Portion of green polar-bear hair, showing medulla with lateral ducts (some communicating with outer surface: arrow) containing algal cells. Phase-contrast; scale bar, 100 μm .

The interior surfaces of the lumina of the narrower guard hairs were smooth. Many of those of intermediate width had pits and channels, more or less perpendicular to the hair axis, extending part of the way to the surface. Some were expanded into chambers parallel with the hair axis, especially near the broken distal end. Those of the stoutest hairs had very many such transverse channels (5–10 μm wide), some extending fully to the outer surface. These features, visible by light microscopy (Fig. 1*a, b*), could be clearly seen in stereoscan electron micrographs of sectioned hairs (Fig. 1*c, d*), which also showed pits in the hair surfaces where some of the side channels opened to the outside (Fig. 2*a, b*).

We have been unable to find any reference to such lateral ducts in the hairs of any mammal¹. Hairs of comparable size from the head, shoulders and flanks of two wild polar bears from Spitzbergen, killed at Isfjord in May 1912 and at Svalbard in July 1967 were white, as were those of three bears obtained this year at L. Churchill, Manitoba: they had similarly hollow medullae but lacked any signs of lateral channels or of algae. (Hairs from four other marine mammals, a sea-otter (*Enhydra*), a northern fur seal (*Callorhinus*), a California sea-lion (*Zalophus*) and a harbour seal (*Phoca*), appeared solid: they too were alga-free.) It is possible that the transverse ducts were formed by keratolytic bacteria, which initially entered the lumina through

broken distal ends. However, in the sections of green bear hairs examined by electron microscopy we saw little evidence of bacterial degradation of the keratin (Fig. 2*c, d*).

The fact that some of these lumina were in connection with the external air or water could explain how the algal cells could have entered the hairs in the first place, and how exchange of O_2 and CO_2 and uptake of water and mineral salts would be facilitated and could permit growth of the algae if suitably illuminated. Indeed, such a habitat has certain advantages, being warm and protected from most kinds of potential predators.

The algal cells from the green zoo bears were spherical, 2–4 μm in diameter. They were clearly prokaryotic; no plastids or nuclei could be distinguished, either by phase-contrast microscopy or in thin sections examined under the electron microscope. They divided by equatorial constriction; no other mode of reproduction was seen. In size and form they resembled *Aphanocapsa montana* Cramer, a blue-green alga in the order Chroococcales, though they appeared more green than blue-green.

Pure cultures were obtained by grinding a washed sample of the green hairs with sterile mineral nutrient medium in a Potter-type homogeniser and streaking a drop of the supernatant algal cell suspension on a 1% agar medium containing mineral nutrient salts². The cells were constantly illuminated at ~2,000 lux from cool-white fluorescent lamps at 27°C. After a week, individual algal colonies were visible under low magnification. Virtually all colonies were of the same size and form, confirming what had already been indicated by microscopic examination of the hairs, that is, that their algal cells were almost all of one type. (Among hundreds of thousands of colonies, only a dozen were of an evidently different kind: a filamentous blue-green alga, similar to *Phormidium*, with cells <2 μm wide.) Apparently clean colonies were selected, transferred to liquid Maertens' medium and illuminated in the same way. When tested on medium supplemented with 0.1% yeast extract, although most were contaminated with bacteria, a few were axenic. Pure cultures were subcultured in Maertens' medium in flasks on a shaker; they grew well, and were comparable in colour, cell size (2.5–4.5 μm), form and fine structure with those observed in the bear hairs (Fig. 3*a*). They required no organic factors for growth. In older cultures, possibly depleted

Phase-contrast; scale bar, 100 μ m.

of a fixed source of nitrogen, the cells became enveloped in colourless mucilaginous sheaths (Fig. 3*b*) which often developed asymmetrically. Growth was most rapid at 33 °C; above 36 °C the algae did not grow. When tested in a range of salinities they behaved like many freshwater species; at salinities below one-third sea water they grew well, but at higher concentrations growth was inhibited. Although we know of no record of keratin digestion by any alga, we tested for this by incubating sections of white polar-bear hairs with a pure culture of this alga in a mineral medium constantly shaken with air at 27 °C in white light. After 12 weeks, although cells grew in the lumina, we could see no indication of erosion of the hairs.

The cultured algal cells were usually bright green. When extracted with non-polar solvents they were found to contain chlorophyll *a* (but no chlorophyll *b*) and various carotenoids. When grown in white light, the cells produced no detectable phycobilin pigment; but when grown in red light they developed a distinctly bluish tinge and formed appreciable amounts of phycocyanin (tested by *in vitro* absorption and fluorescence spectra). We therefore concluded that the alga is a cyanophyte.

Similar cultures were isolated in the same way from hairs of the green polar bear at Fresno, mentioned above. Apparently the alga commonly infests the hairs of polar bears in zoos. It is a freshwater species, the cells of which probably originate from the pond water in the bears' enclosures and enter the medullary lumina of the guard hairs through broken distal ends or through the patent lateral ducts.

Few other chordates are known to harbour algae on their surfaces. Certain colonial ascidians in the family Didemnidae are associated with prochlorophytes³. Freshwater turtles may bear branched filamentous chlorophytes in the genus *Basiacladia*⁴. Unidentified green algae may colour the pelage of monk seals (*Monachus*)⁵, while brown or red algae (*Ectocarpus*, *Erythrocladia*) have occasionally been found growing on the hairs of fur seals⁶. On two-toed and three-toed sloths (*Bradypus* and *Choleopus*) grooves on the outer surfaces of their guard hairs bear algae of two kinds; filamentous chlorophytes assigned to the genus *Trichophilus* (Chaetophorales) and purple cyanophytes which have been called *Cyanoderma* (Chamaesiphonales)⁷. Several genera of pennate diatoms grow on the skin of various kinds of whales, including the 'sulphur-bottomed' whale⁹. These algae are all quite unlike the species found in hairs of captive polar bears, described here. The African prosimian primate *Galagoides* has been reported to have green algae associated with its fur⁸, but this could not be confirmed.

We thank Dr Lanna Cheng for the stereoscan electron micrographs, Dr Norman McLean for transmission electron micrographs of thin sections of alga-infested hairs and Drs William Vidaver and Nancy Withers for the information on photosynthetic pigments. This work was partly supported by NSF grant 76-21405 (to R.A.L.).

Receptor for IgG(Fc) and human β_2 -microglobulin on *S. mansoni* schistosomula

HOST antigen uptake by schistosomes is generally considered from circumstantial evidence to be a potent mechanism by which schistosomes can evade immune response and has therefore stimulated several investigations on the chemical nature of the molecules as well as their possible mode of incorporation¹. These studies have indicated that the parasite can acquire host material in the form of glycolipids of erythrocyte origin² and gene products of the murine major histocompatibility complex³. As an alternative to host antigen incorporation, the possibility of immunological blockade has been suggested. Host immunoglobulins have been demonstrated to be associated with the tegumental surfaces of *Schistosoma mansoni* from mice and baboons, and recent experiments^{4,5} have shown the presence of

Fig. 1 Photomicrographs ($\times 100$) of characteristic rosette formation (EA) with sensitised sheep RBC on the surface of different life stages of schistosomula. Schistosomula collected *in vitro* after skin penetration show complete rosetting EA (a). Schistosomula obtained after mechanical disruption of the cercarial tail show EA rosettes capped (b) at the anterior part of the parasite. No rosette formation is observed when 5-d-old schistosomula collected by lung recovery are used (c).

heterospecific antibody on the tegumental surface of *S. mansoni* adult worms. The ability of adsorbed antibodies to bind their respective antigens indicates that some of these immunoglobulins are orientated so as to present at least one free Fab region of the antibody molecule. Although this could merely represent a nonspecific adsorption, it could also represent the specific binding of the immunoglobulin on the parasite's surface. Using a rosette test we have now demonstrated the presence of receptors for both IgG(Fc) and human β_2 -microglobulin.

Sheep erythrocytes (RBC) were sensitised with mouse anti-sheep erythrocyte antibody (EA) to form rosettes, after which the cells were washed and placed in contact with schistosomula obtained *in vitro* after skin penetration according to Clegg and Smithers⁶. In other experiments schistosomula were incubated for 30 min with mouse anti-sheep RBC antibody, washed and placed in contact with normal sheep erythrocytes. In these two experimental conditions, rosette formation was observed around schistosomula which seemed to be almost totally coated with erythrocytes (Fig. 1a). When cercariae collected before skin penetration or 5-d-old schistosomula (Fig. 1c) collected by lung recovery in infected mice were used, no rosette formation was observed (Table 1). Schistosomula, obtained without skin penetration, after mechanical disruption of the cercarial tail⁷,

Table 1 Rosette formation at different life stages of *Schistosoma*

Artificially transformed schistosomula	++	—
5-day lung schistosomula	—	—
Adult worms	—	—

Sheep erythrocytes stored in Alsever's solution were washed three times with 0.15 M NaCl and suspended to 3×10^8 cells ml^{-1} in phosphate-buffered saline (PBS), pH 7.2. Equal volumes of 1/1,000 diluted mouse anti-sheep erythrocyte serum were added to the red cell suspension and incubated at 37 °C for 60 min. The sensitised cells were washed three times with PBS and used for the EA-rosette formation. 50 washed larvae or 10 adult worms were incubated with 5×10^4 sensitised red cells in a final volume of 1 ml hydrolysate lactalbumin Earle's glucose (HLEG) at 37 °C for 30 min. After gentle resuspension, rosette formation was observed. Larvae or worms surrounded by more than five red cells on the surface were scored as positive. The intensity of the rosetting was graded from ++ (partial erythrocyte binding, >30 RBC) to +++ (totally coated with erythrocytes).

showed a partial erythrocyte binding (Fig. 1b) usually starting at the anterior end of the parasite, which becomes totally coated within 1 h of *in vitro* incubation.

The specificity of the schistosomula binding site for immunoglobulins was assessed with various heterologous proteins of an approximately similar molecular weight. Previous incubation at a concentration of 1 mg ml^{-1} for 30 min at 37 °C with ribonuclease I (Worthington), cytochrome *c* from horse heart (type VI, Sigma) or lysozyme from egg white (grade I, Sigma) did not inhibit rosette formation, whereas inhibition was observed on incubation with immunoglobulin from different animal species (man, rabbit, mouse, rat) (Table 2). Specificity for IgG binding was similarly studied by various inhibition experiments. Incubation of schistosomula with unaggregated (100 $\mu\text{g ml}^{-1}$) or aggregated (1 mg ml^{-1}) IgG (Table 2) from different animal species (man, rat, mouse and rabbit) entirely inhibited subsequent rosette formation, whereas incubation with IgA, IgM or IgE had no inhibitory effect (Table 2). Evidence for the specific binding of IgG to a possible Fc receptor was indicated by two series of experiments.

Table 2 Specific inhibition of EA rosettes by IgG or Fc γ on skin schistosomula

Schistosomula	Sensitised sheep RBC
Non-incubated	+++
Previously incubated with:	
Human, rat, mouse and rabbit Ig	—
Human IgM, IgA, IgE (50 $\mu\text{g ml}^{-1}$)	+++
Unaggregated (100 $\mu\text{g ml}^{-1}$) or aggregated human IgG (1 mg ml^{-1})	—
Fc fragments of human IgG (40 $\mu\text{g ml}^{-1}$)	—
F(ab') ₂ fragments of rabbit anti-human IgG (10 $\mu\text{l ml}^{-1}$)	+++

In each experiment, 50 larvae were preincubated with components adjusted to appropriate concentrations with 1 ml HLEG at 37 °C for 30 min and washed three times with HLEG before addition of sensitised sheep red blood cells. The intensity of the rosetting was graded as in Table 1. The purity of IgA (α I subclass) or IgM each with λ light chains was verified by the Ouchterlony technique. Fc fragments were prepared according to the method of Porter⁹ with papaine, and purified on DEAE-cellulose (0.3 M NaCl). F(ab')₂ fragments of rabbit prepared by pepsin digestion (ratio: 1/50, 10 mg ml^{-1} proteins in 0.1 M sodium acetate, pH 4.5, 24 h, 37 °C) were purified by gel filtration through Sephadex G-200. The purity of fragments was verified by immunoelectrophoresis against specific antisera.

When schistosomula were incubated with Fc fragments of human IgG, total inhibition of rosette formation was observed, whereas incubation with rabbit IgG F(ab')₂ anti-human IgG did not affect erythrocyte binding (Table 2). On the other hand, no rosette formation was observed when schistosomula were incubated with ox erythrocytes sensitised with an F(ab')₂ fraction prepared by pepsin digestion from rabbit anti-ox RBC IgG (Table 3) and with an anti-ox RBC 19S fraction purified from rabbit (Table 3).

Enzyme sensitivity of the Fc receptor was also estimated by rosette inhibition experiments. Fc receptors on schistosomula were found to be trypsin resistant (trypsin TRTPCK, Worthington) (0.5 mg ml^{-1} for 30 min at 37 °C) and pronase (Calbiochem) (0.5 mg ml^{-1} for 30 min at 37 °C) sensitive. Results of binding of radioiodinated IgG to Fc receptors on schistosomula will be published elsewhere (G.T., in preparation).

The experiments reported here indicate the existence on schistosomula of a specific binding site for the Fc portion of IgG possessing the specificity of Fc γ receptors described on eukaryotic cells. The appearance of the above described receptors seems to follow a dynamic process during the early stages of the parasite life cycle. It was observed that although free-living

Fig. 2 Inhibitory effect of human β_2 -microglobulin on EA-rosette formation. Schistosomula collected *in vitro* after mouse skin penetration were washed three times with large volumes of HLEG. For use in the inhibition assay, 50 larvae were incubated in 1 ml HLEG with different amounts of β_2 -microglobulin with frequent mixing at 37°C for 30 min. Schistosomula were then washed in HLEG and the rosette formation was observed with sensitised sheep RBC (EA) prepared as described in Table 1. Larvae surrounded by less than five red cells on the surface were counted as negative and their percentages were calculated from at least 30 schistosomula.

cercariae did not express these surface receptors, maximum density of binding sites was observed by rosette formation on 3-h-old schistosomula collected after skin penetration. Strikingly, newly transformed schistosomula collected after mechanical tail disruption showed a progressive appearance of binding starting at the anterior end of the parasite, near the glandular apertures, and extending to the whole body within 1 h of *in vitro* incubation. This dynamic process might be related to the excretion of parasite enzymes known to occur during this period⁶. In the later life stages of the parasite, 5-d-old schistosomula and adult worms no longer express the ability to form rosettes.

The binding of IgG to the Fc receptor on eukaryotic cells is not inhibited by β_2 -microglobulin despite the homology between this molecule and the third domain of the γ chain. As histocompatibility antigens are known to bind to schistosomula³ we investigated whether β_2 -microglobulin interfered with EA rosetting. When schistosomula were first incubated with human β_2 -microglobulin (Pharmacia), total inhibition of rosette formation was observed at a concentration of 5 ng ml⁻¹ for 30 min at 37°C (Fig. 2).

The present results indicate that IgG binds to *S. mansoni* schistosomula. The affinity of the receptor for β_2 -microglobulin suggests two possibilities: (1) a receptor for IgG which, because of the phylogenetic distance between trematodes and mammals presents some unusual features and is mostly for the third domain of the γ chain, or (2), a receptor for β_2 -microglobulin

Table 3 Rosette formation on schistosomula using ox RBC and anti-ox RBC antibody

Ox RBC sensitised with:	Rosetting
Anti-ox RBC IgG (rabbit)	+++
Anti-ox RBC 19S (rabbit)	—
F(ab') ₂ fragments of rabbit anti-ox RBC IgG*	—

Ox erythrocytes stored in Alsever's solution were washed three times with Hank's balanced salt solution (HBSS) and suspended to 2×10^8 cells ml⁻¹ in HBSS. Sensitised ox RBC (EA) were prepared in the usual way with rabbit IgG anti-ox-RBC isolated by column chromatography with DEAE Sephadex A-50, rabbit 19S anti-ox RBC passed through a Sephadex G-200 column and an F(ab')₂ fraction prepared by pepsin digestion from rabbit anti-ox RBC IgG.

binding IgG through the homology with its third domain. In any case, the receptor might be involved in the specific binding of murine major histocompatibility antigens³ on schistosomula in addition to that of IgG. The precise relationship between these two host antigens is still under investigation.

This work was supported by the CNRS (ERA 422), the INSERM (G.R. 167) and the WHO Special Programme for Research and Training in Tropical Diseases. IgM and IgA were provided by Drs M. Seligmann and F. Danon, IgE was from Pharmacia, immunoglobulin fragments from Drs C. Ropartz and D. Rivat, and isolated Ig fractions and ox RBC from Dr M. Revillard.

Demonstration of MHC-specific haemolytic plaque-forming cells

It would be convenient to be able to measure the antibody response to alloantigens of the major histocompatibility complex (MHC) at a cellular level. As MHC alloantigens are expressed on erythrocyte membranes in mice one might suppose that a conventional Jerne plaque assay with enumeration of haemolytic plaque-forming cells (allo-PFC) against a lawn of

Fig. 1 Synergistic lysis of DA erythrocytes by two monoclonal AO anti-DA alloantibodies, R2/15P (HLGK) and R2/15S (HL) compared with the AO anti-DA antiserum S.006. (—) R2/15P (○) and R2/15S (●) were titrated alone, and R2/15P titrated additionally in the constant presence of a 1/32 dilution (final) of R2/15S (○). Marked synergy between the two monoclonal antibodies is apparent. Their activity together resembles that of the antiserum. Fresh DA erythrocytes were labelled with ⁵¹Cr-Na₂CrO₄ as described previously⁴. Guinea pig serum used as a source of complement at 1/8 (final) was absorbed with 2×10^6 packed rat blood cells before use. The assay mixture was incubated for 1 h at 37°C in V-bottomed microtitration trays.

Fig. 2 Plaque formation by spleen cells from an AO rat immunised against DA lymphoid cells (AO 1; see Table 1 legend for immunisation and technical details). 5×10^5 cells per Cunningham chamber: a, No additional reagents added to the assay; b, R2/10P (HL) monoclonal anti-DA (H-1A^a) antibody added at 1/30 final; c, R3/47 (HL) monoclonal anti-DA antibody added at 1/10 final. ($\times 2$.)

suitable allogeneic erythrocytes would be straightforward. In fact such assays have proved difficult, with very few plaques being detected^{1,2}. We have found the same problem in detecting allo-PFC in the spleens of alloimmunised rats. Although alloantisera raised in appropriate strain combinations have a high titre in a direct complement dependent haemolytic assay (Fig. 1) emphasising the potential value of this convenient assay for alloantibody in the rat^{3,4}, very few allo-PFC were found in spleen cell suspensions from hyperimmunised donors. We show here that the discrepancy may be due to the homogeneity of the antibody product of a single PFC compared with the heterogeneity of serum antibody.

During a study of the haemolytic properties of monoclonal anti-rat MHC (H-1) alloantibodies generated by somatic cell hybridisation^{4,5} we observed that of six monoclonal anti-H-1A^a IgG antibodies studied none was able to lyse more than a proportion (<50%) of DA (H-1A^a) erythrocytes at saturation, whereas mixtures of appropriately chosen pairs of monoclonal antibodies would regularly lyse 100% of erythrocytes (Fig. 1). The principal factor limiting cell lysis by a single monoclonal alloantibody was determinant density on the target cell⁵. Recent data demonstrate that erythrocyte populations are heterogeneous in H-1A^a determinant density and that cells with high determinant density are lysed preferentially by a single monoclonal alloantibody (unpublished results). The determinant density dependence of lysis is radically reduced when appropriate mixtures of monoclonal antibodies are used. The definition of 'appropriate' in this context is that the two monoclonal antibodies used should bind noncompetitively to different determinants on the same target molecule. In these conditions, for reasons which are not yet clear, the two antibodies synergise strongly in lytic activity⁵.

The failure to demonstrate allo-PFC in the spleens of hyperimmune donors may therefore have been due to the fact that only a small proportion of erythrocytes was lysed by the monoclonal antibody product of each potential plaque-forming cell resulting in 'plaques' that were too faint to be seen. It therefore seemed likely that if one component of a synergistic pair of monoclonal antibodies was added to the plaque assay system in excess, clear plaque formation would occur around a cell secreting a complement fixing antibody that was not competitive with the exogenous antibody. Spleen cells taken from AO (H-1^a) rats 6 and 7 days after an intravenous boosting immunisation with DA (H-1^a) lymphoid cells showed the characteristic low but measurable allo-PFC activity in conventional Cunningham⁶ plaque chambers. When exogenous monoclonal anti-H-1A^a antibodies were added to the chambers an enormous increase in plaque count was seen (Table 1, Fig. 2). The size of the increment was a function of the monoclonal antibody added: three monoclonal antibodies probably directed against the same determinant⁵ (R2/10P, R2/15P and R3/13) were highly efficient in developing plaques. Monoclonal antibodies directed against another part of the molecule (R2/10S, R2/15S and R3/47) were less efficient. This order has been maintained (with the single exception of AO4) in all animals assayed (Table 1 and unpublished results). It was also noticeable that plaques forming in the presence of R2/10P, R2/15P and R3/13 were larger than those forming with the other antibodies (Fig. 2). It is therefore possible that the differential efficiency is a reflection of differential visibility of plaques. Alternatively, each group of antibodies might allow a distinct subset of the plaque-forming cell response to be seen (that is those producing antibody not competitive with the added monoclonal antibody) and that the subsets are regularly of different sizes.

Table 1 Demonstration of allo-plaque-forming cells using synergistic lysis with monoclonal alloantibodies

Antibody added*	Plaque-forming cells per 10^6 spleen cells

AO ♀ rats at 3–4 months old were immunised against DA spleen and lymph node cells by primary subcutaneous and intraperitoneal injection on day 1, followed by an intravenous boosting injection of DA lymphoid cells at day 142 (rat 1), day 43 (rats 2 and 3), or days 43 and 72 (rats 4 and 5). Spleen cells were taken 6 days (rats 1–3) or 7 days (rats 4 and 5) after the i.v. boost, suspended in Dulbecco's phosphate-buffered saline containing 2% fetal calf serum (DAB/FCS), and diluted to an appropriate concentration for assay. Fresh DA erythrocytes were washed in phosphate-buffered saline and diluted to a 25% suspension in DAB/FCS for use. Guinea pig serum absorbed 1:4 with DA blood cells was used as a source of C' at a final concentration of 1/10. Plaque assays were incubated in Cunningham chambers for 60 min at 37°C.

* Monoclonal antibody supernatants were used at final concentrations between 1/10 and 1/30 in the plaque-forming cell assay with the exception of R2/10S on AO 2. In this case the supernatant was concentrated 10-fold by $(\text{NH}_4)_2\text{SO}_4$ precipitation between 50% and 60% saturation and used finally at 1/10, equivalent to undiluted supernatant.

† Anti-rat IgG was a rabbit anti-rat IgG2 antiserum (JH 1/7) used at a final (optimal) dilution of 1/30. Other anti-Ig reagents were also used in some experiments. Plaques detected with anti-Ig reagents were always small and hard to score.

Synergistic lysis by monoclonal antibodies is usually a more efficient method of demonstrating allo-plaque formation than is the addition of heterologous antiglobulin antisera (Table 1). Plaques developed by anti-IgG reagents were usually small and hard to score. This low efficiency is presumably partly responsible for the variations recorded in anti-Ig plaque scores in Table 1. We have no direct evidence that the plaques seen in the synergy experiments are produced by IgG antibody. However, since the synergistic lysis phenomenon is only known by us from IgG monoclonal antibodies, and since the assays were performed relatively late (6 or 7 days) in a secondary or tertiary response it seems probable that the exogenous monoclonal antibodies do in fact reveal IgG plaque-forming cells. It may be that the small numbers of plaques seen without the addition of a synergistic monoclonal antibody represent IgM secreting cells. We do not have an IgM anti-H-1A^a monoclonal antibody but such an antibody would be expected to be less dependent on determinant density for its lytic activity. It may be that the H-1A^a specificities are particularly suitable targets for demonstrating the synergistic development of PFC by monoclonal alloantibody, as there is evidence that these specificities are unusually abundant on erythrocytes of the DA strain⁷. However, haemolytic antisera may be raised against other haplotypes³.

The phenomenon of synergistic lysis explains why only very few allo-PFC could be detected in animals producing high titre haemolytic antisera: a lytic alloantiserum is a synergistic antibody mixture.

The beige mutation in the mouse selectively impairs natural killer cell function

GERM LINE mutations affecting defined cell populations are often valuable tools in elucidating the function of these cells in complex biological systems such as tumour rejection. We report here that a mutant gene in the mouse called *beige* (*bg*⁺), leads to a complete and selective impairment of naturally occurring killer lymphocytes, whereas all other forms of cell-mediated lysis are apparently normal. The defective gene product may lie within the lytic pathway subsequent to tumour cell contact. Because many cell types, including natural killer (NK) cells, T cells and macrophages, may be involved in tumour resistance *in vivo*¹, these mice will provide a critical test of the hypothesis that it is NK cells which provide a first line of defence against neoplasia². It is likely that this mutant will be invaluable for further investigations in tumour immunology just as the nude mouse has been indispensable in evaluating the role of the

thymus in the development of the T-lymphoid system and the role of T cells in the rejection of tumours.

The *beige* mutation in C57BL/6 mice occurred spontaneously in an autosomal recessive gene on linkage group XIV (ref. 3) and is thought to provide an accurate model of the Chediak-Higashi syndrome in man⁴. Humoral immunity and delayed-type hypersensitivity are normal and the chief cause of mortality is an increased susceptibility to infection⁵ and a lymphocytic infiltration which may be malignant⁶.

Fig. 1 The absence of NK-mediated cytotoxicity in *beige* mice. Nylon wool column-passed spleen cells from 4-week-old mice were incubated with ⁵¹Cr-labelled YAC tumour cells at various effector-to-target ratios in a 4-h assay¹¹ (a) or for various periods of time at a 100/1 effector/target ratio (b). ▲, A/Sn; ○, C57BL/6, *bg*⁺/*bg*⁺; ●, *+/bg*⁺ littermates; ■, age-matched *+/+* controls. Values represent the mean % specific lysis ± s.e. in quadruplicate wells.

To investigate NK cell function in mutant mice, spleen cells were passed over nylon wool columns, a procedure which enriches for NK cells (Fig. 1). Compared with one of the lowest responder strains known (A/Sn), it can be seen that the homozygous *beige* mutants (*bg*⁺/*bg*⁺) were completely deficient in their ability to lyse YAC cells, a Moloney lymphoma which is the most sensitive NK target yet described. The heterozygous littermate controls (*+/bg*⁺) responded as well as the wild type (*+/+*). The low response of the *bg*⁺/*bg*⁺ mice was not altered by prolonged incubation times or high effector-to-target ratios. In additional experiments (unpublished observations) the absence of NK cytotoxicity was apparent in all the NK-bearing lymphoid organs (spleen, lymph node, bone marrow and peripheral blood) and at all points in the life cycle whether tested against YAC or other NK-sensitive targets (RBL-5, MPC-11, 136-6, P-52, Molt-4). In addition, interferon or interferon-inducing agents (poly I:C, tilorone) failed to augment lysis in *beige* mice (submitted for publication) whereas these agents greatly augmented NK function in low responder strains such as A/Sn and in very young or old mice of the same strain (Gidlund, personal communication). Therefore, the deficient NK response in *beige* mice cannot be accounted for by an altered tissue distribution, age-dependent maturation or a shift in target selectivities. It was then relevant to consider if the defect in cytotoxicity was selective for NK cells or whether it involved a general failure of all forms of cell-mediated lysis.

As shown in Table 1 (lines 4-6), cytotoxic T lymphocytes generated by alloimmunisation of *+/bg*⁺ or *bg*⁺/*bg*⁺ mice *in vivo* or by one-way mixed lymphocyte cultures (MLC) *in vitro* were equally capable of lysing P815 cells (a completely NK-insensitive target). In addition, spleen cells from *bg*⁺/*bg*⁺ mice alloimmunised *in vivo* responded to secondary challenge in MLC cultures by mounting a strong response on day 3. Peak responses in primary MLC cultures were not obtained until days 5 or 6. Further experiments revealed identical kinetics of cytotoxic

Lines 1, 2, 3: spleen cells from untreated mice were tested in a 4-h ⁵¹Cr-release assay against normal YAC targets (Moloney lymphoma from A/Sn, H-2^{kd}) or P815 cells (DBA/2 mastocytoma, H-2^{dkd}) and chicken erythrocytes treated with a predetermined optimum concentration of specific antibody (1/80 A.BY × C57Bl/6 F₁ anti-A/Sn and 1/200 mouse anti-CRBC, respectively). P815 and CRBC targets treated with normal serum or untreated yielded <2% lysis. Line 4: mice were injected intraperitoneally on day -10 with 30 × 10⁶ P815 cells (passage 25 *in vitro*) and pooled spleens were assayed in a 2.5-h ⁵¹Cr-release assay. Lines 5, 6: spleen cells from untreated mice or mice immunized *in vivo* with P815 (line 4) were cultured with mitomycin C-treated DBA/2 spleen cells at a 5/1 responder/stimulator ratio. Primary (1st) and secondary (2nd) cultures were collected on days 5 and 3, respectively, and assayed in a 2.5-h test. Non-stimulated control cultures yielded <15% lysis of P815 and stimulated cultures failed to lyse RBL-5 cells (H-2^{dkd}). Line 7: mice were injected intravenously at -24 h with 250 µg Con A and spleen cells were assayed in a 16-h ⁵¹Cr-release test in the presence of 10 µg ml⁻¹ Con A. Con A did not affect target cell survival and was necessary for maximum lysis *in vitro* as described previously. Line 8: bone marrow cells were cultured as previously described and on day 3, non-adherent cells (promonocytes) were removed and cultured with lymphokine derived from the supernatants of 24 h, Con A-stimulated C57Bl/6 spleen cells. The 'activated' macrophages which adhered to glass were cultured for 16 h with ⁵¹Cr-labelled P815 target cells. Non-activated control cultures yielded <5% lysis.

* Cytotoxicity by effectors designated as CTL was inhibited over 90% by anti-θ serum and guinea pig complement whereas NK cells were inhibited <10%. Neither CTL nor NK was affected by pretreatment with carbonyl iron and a magnet. Incorporation of heat-aggregated mouse gamma globulin (1–500 µg ml⁻¹) into the cytotoxic assay blocked 70% of ADCC against chicken erythrocytes (CRBC) but had no effect on lysis by NK cells, CTL or ADCC against P815. All responses of age-matched +/+ mice were similar to those of heterozygous littermate controls, +/bg^j, and therefore the wild-type values have been omitted for clarity.

† All targets were maintained by continuous *in vitro* culture except CRBC.

‡ A lytic unit was defined as the number of effector cells required for 50% maximum lysis and was calculated from parallel effector titration curves over the entire range of lysis from 0 to maximum.

§ The values given represent the mean % lysis in quadruplicate wells at the effector/target ratio given in brackets. These levels of lysis were designated as the maximum attainable, as they occurred on the plateau of effector titration curves.

T-lymphocyte generation in MLC cultures and the kinetics of target cell lysis in the cytolytic assay also overlapped (unpublished data). In addition, the normal level of lysis in *beige* mice by T cells activated with concanavalin A (Con A) indicates that the total pool of cytotoxic T cells is normal, as this technique is thought to measure all polyclonally distributed killer T cells regardless of their specificity⁸. These results strongly suggest that T cells from *beige* mice are capable of exerting normal cytolytic function.

Tumour cell destruction by other cells types also seemed normal in *beige* mice (Table 1, lines 8, 9). Bone marrow-derived macrophages activated *in vitro* with a lymphokine⁹ lysed P815 cells, as did peritoneal macrophages when activated with lipopolysaccharide¹⁰ (unpublished observation). Antibody-dependent cell-mediated cytotoxicity (ADCC) against antibody-coated chicken erythrocytes (CRBC) was also normal in *beige* mice (Table 1, line 2). As ADCC against CRBC in the mouse is mediated largely by Fc⁺, adherent cells^{11,12}, this population seems to be normal. In addition, the killing capacity of monocytes and granulocytes may also be normal in *beige* mice, as these effectors are involved in human ADCC against CRBC¹³. ADCC against tumour cells, however, is mediated by different lymphocytic effectors called K cells¹. As shown in Table 1, line 3, the function of these cells is completely deficient in the homozygous *beige* mice; this provides the strongest evidence that murine K cells and NK cells are identical, as suggested by Ojo and Wigzell¹². These workers showed that antibody-coated, NK-insensitive P815 cells competed with non-antibody-coated, ⁵¹Cr-labelled YAC cells in a cytolytic assay¹². However, murine NK and K cells directed against tumour cells do not possess readily detectable Fc_γ receptors, as direct lysis of antibody-coated P815 cells is not inhibited by aggregated gamma globulin, as reported earlier¹¹ and confirmed here (Table 1). It is possible, therefore, that non-antibody-dependent contact with a target

triggers the expression of Fc receptors in the NK cell which can then kill by either an antibody-dependent or antibody-independent mechanism, depending on (1) the availability of antibody on the target cell and (2) the NK sensitivity of the target.

The detailed nature of the NK defect in *beige* mice is not known, but may lie within the lytic machinery of the cell rather than at the level of population size or recognition receptors. As shown in Table 2, nylon-passed spleen cells from *bg^j/bg^j* mice were completely normal in their capacity to bind to YAC targets. We have previously shown that this assay is a reliable measure of the frequency of NK cells in a mixed population^{14,15}. The target-binding lymphocytes from *beige* mice were selective,

Table 2 The frequency of target-binding cells in *beige* mice

Genotype	Preincubation of effectors*	% Target-binding cells
C57Bl/6 (+/+)	None	20.4
	NK-TS	8.1
C57Bl/6 (+/bg ^j)	None	19.8
	NK-TS	9.2
C57Bl/6 (bg ^j /bg ^j)	None	21.3
	NK-TS	7.9
A/SN	None	7.6
	NK-TS	3.4

Nylon wool column-passed spleen cells from age and sex matched mice were labelled with fluorescein and incubated with a 10-fold excess of YAC cells. The number of lymphocytes binding to YAC was then determined by counting 500 cells in an ultraviolet microscope¹⁴. Additional spleen cells were preincubated for 1 h at 4 °C with 1 µg of 140 K glycoprotein isolated from YAC membranes and purified by SDS-polyacrylamide gel electrophoresis¹⁶. The inhibition of subsequent binding to intact YAC was dose dependent and was not observed when similar concentrations of purified H-2^{kd} antigen was used. NK-TS, natural killer cell-target structure, a glycoprotein isolated from YAC cells¹⁶.

as they could be inhibited by preincubation with solubilised and purified NK target antigens from YAC but were not inhibited by H-2 antigen prepared in the same manner, as previously documented in other strains¹⁶. Further experiments are necessary to localise the defective gene product in the lytic pathway subsequent to target cell contact.

In conclusion, we have described a genetic impairment in the lytic machinery of NK cells which totally prevents these cells from initiating antibody-dependent or antibody-independent cytotoxicity of tumour cells. This defect was selective for NK cells, as lysis by immune T cells, macrophages and cells participating in ADCC against a non-tumour target was normal. Additional experiments, designed to test oncogenesis and spontaneous tumour development in these mutant mice, will provide a critical test of the hypothesis that NK cells are involved in surveillance against neoplasia.

The data showing normal macrophage killing in *beige* mice has recently been confirmed and extended by Marie-Luise Lohmann-Matthes.

Amyloid resistance in A/J mice is determined by a single gene

WIDESPREAD tissue deposition of the unique fibrous protein amyloid occurs in a variety of human diseases¹. 'Secondary' amyloidosis arises as a complication of chronic infectious or inflammatory disease and an identical syndrome can be induced in mice by repeated injections of casein². Little genetic work has been done in this area, probably because development of amyloidosis is often variable, even with a standard induction regimen, and results are inconsistent³. Furthermore, because of the many complex immunological aberrations occurring during the

amyloid induction period⁴, the various experimental manipulations which can affect it⁴, and the wide range of induction times seen in different murine strains², one would expect that multiple genes and alleles would influence amyloidogenesis. Nevertheless, the discovery of the uniquely resistant A strain⁵ suggested the possibility of isolating at least part of the genetic basis for amyloid susceptibility or resistance. We now report a genetic analysis of amyloid induction in two inbred strains, CBA/J and A/J, differing markedly in susceptibility to amyloidosis⁵. We show for the first time that a single gene confers resistance on the A/J strain. Our results imply that genetic factors may also define subpopulations of chronic disease patients who are at greater risk from amyloid disease.

Table 1 No. of mice in each group resistant to a 6-week period of amyloid induction by azocasein

Group	No. tested	No. resistant
CBA/J	20	0
(CBA × A) _{F1}	20	0
A/J	20	20
F ₁ × A/J	43	19

Although we have generally used casein in our experimental protocols, the more potent, predictable amyloidogen azocasein⁶ was chosen for these experiments. We find that five subcutaneous injections per week of 10% azocasein induces amyloid in 100% of the highly susceptible CBA/J strain within 2 weeks. Induction time has been consistent with different batches of azocasein and in different experiments, in contrast to our experience with casein. F₁ hybrid mice were produced by mating CBA/J females with A/J males. Preliminary work established that although all CBA/J mice had amyloidosis after 2 weeks of azocasein, 3-4 weeks were required to achieve a 100% incidence in F₁ hybrids. In contrast, the earliest appearance of amyloid in A/J mice was at 7 weeks, with a less than 30% incidence after 8 weeks of injections. We tentatively concluded that although the F₁ heterozygous mice had a slightly prolonged amyloid induction period, the marked resistance of the A/J strain was a recessive trait.

For the definitive genetic experiment, females of the F₁ hybrid group were mated to A/J males. CBA/J, F₁ hybrid, backcross and A/J mice were subjected to serial azocasein injections, five per week, and congo red-stained spleen sections were then scored for the presence or absence of amyloid. F₁ hybrid mice were studied after 2 or 4 weeks of injections. An induction period of 6 weeks was selected for backcross mice, as this is well beyond the period required to induce a 100% incidence of amyloid in F₁ hybrid mice, but too soon to produce amyloid in any A/J mice. Groups of A/J mice were studied after 6, 7 or 8 weeks of injections. Under this protocol we expected that only those backcross mice with resistance similar to that of the A parent would remain free of amyloid. The percentage of amyloid-resistant mice in the backcross group would allow an estimate of the number of genes involved in determining resistance. The results are shown in Table 1. In agreement with preliminary experiments, 100% of CBA/J mice had amyloid when studied at 2 weeks and 100% of F₁ hybrids had amyloid at 4 weeks. After 6 weeks, no amyloid was found in A/J mice, although one of six A/J animals had amyloid after 7 weeks (not shown), demonstrating that 6-7 weeks is the threshold for amyloid induction in the A strain in these laboratory conditions. In the backcross group, 19 of 43 animals were resistant to 6 weeks of azocasein injections. This is close to the 50% incidence of amyloid resistance expected if it were the expression of a single gene, and significantly greater than the 25% incidence expected for a trait requiring two genes.

In contrast to other groups, there was a different incidence of amyloid in males and females of the backcross group; 13 of 22

females but only 6 of 21 males were resistant (data not shown). In addition, male spleens contained histologically more amyloid than female spleens. A simple explanation for this is that males of this group in particular demonstrated considerably more fighting than other groups of mice. As wounds from fighting alone are a major cause of amyloidosis in male mice⁷, and as inflammation correlates with amyloidosis⁸, the biting and clawing of injection sites observed in these mice would be expected to increase amyloid production. Therefore, the incidence of resistance in 13 of 22 female mice probably represents the 'true' incidence.

We are not proposing that a single genetic locus alone governs susceptibility to amyloid. The genetic data presented here, however, demonstrate that a single gene with a major influence on amyloidogenesis can account for the extreme degree of resistance seen in the A strain, compared with CBA mice.

The mechanism of amyloid resistance remains unknown, but several possibilities are suggested by previous work. The inducing agent casein has been demonstrated to be a polyclonal B-cell activator in the susceptible CBA strain⁹. Although genetic analysis of this B-cell response was not carried out, the genetics of B-cell response to lipopolysaccharide, another amyloid-inducing agent, has been extensively studied; a single gene has been shown to account for variation in macrophage and B-cell responsiveness to this agent¹⁰. The role of B-cell activation in amyloid production is not known, but differences in B-cell function during amyloid induction in CBA and A mice have been demonstrated¹¹. Thus, a single gene determining B-cell responses to azocasein is plausible by analogy to other systems.

A very different hypothesis is suggested by recent work on the cellular degradation of the AA protein, a major amyloid component, and SAA protein, its serum precursor¹². Although three different patterns of breakdown of SAA were observed, one particular pattern of enzymatic breakdown was found in all amyloid patients but only some normal controls¹². If a single enzyme system involved in degradation of SAA protein is indeed a critical factor in amyloidogenesis, then a single genetic locus could very well have a major influence on amyloid susceptibility, as suggested by the data presented here.

The present data do not allow us to choose between these or other hypotheses accounting for the unusual amyloid resistance of the A/J strain mouse. However, the demonstration that a single genetic locus may be the basis for the resistance offers the hope of elucidating one of the critical steps in the pathogenesis of amyloid.

Histamine-coated particles generate superoxide (O_2^-) and chemiluminescence in alveolar macrophages

We have recently shown that histamine bound to red cells forms 'rosettes' with various guinea pig leukocytes and that these 'histamine receptors' are particularly well expressed on the alveolar macrophage¹. As the lung is a major site of histamine storage and high concentrations of histamine are present in the sputum in certain respiratory diseases such as chronic bronchitis and asthma^{2,3}, we have performed experiments to determine whether free histamine, or histamine bound to particles, interacts with its membrane receptor to initiate the respiratory burst in alveolar macrophages. Activation of the respiratory burst in phagocytic cells is achieved by a number of agents, both soluble

Fig. 1 The generation of O_2^- by alveolar macrophages activated with histamine bound to zymosan (HRSZ). Guinea pig alveolar macrophages, obtained by broncho-tracheal lavage, were purified by centrifugation on Ficoll-Hypaque, washed three times with the balanced salt solution (BSS⁺⁺) described previously⁴ and adjusted to a concentration of 2.4×10^6 cells ml^{-1} . This procedure was repeated if there were any contaminating granulocytes. These procedures gave alveolar macrophages of 90-95% purity which were free of granulocytes and red cells, the contaminating cells being virtually all lymphocytes. The cells (0.8 ml) were incubated with 0.1 ml of the various agents indicated or with BSS⁺⁺ to obtain the resting or unstimulated (Unstim.) values. Following addition of cytochrome c (100 nmol in 0.1 ml) in the presence or absence of superoxide dismutase (4.2 nmol in 50 μ l), the mixtures were incubated at 37°C for 30 min, transferred to an ice-bath and centrifuged at 1,000g for 5 min. The O_2^- activity was measured as cytochrome c reduction (calculated from the decrease in absorbance at 550 nm on addition of potassium ferricyanide as described previously⁵) using a Pye Unicam SP 1800 UV spectrophotometer. Any reduction occurring in the presence of superoxide dismutase was subtracted from these values. Histamine dihydrochloride (1.4 g) was conjugated to 200 mg rabbit serum albumin (HRSA) with 1.2 g of 1-ethyl-3-(3-dimethylaminopropyl) carbodiimide (ECDI) contained in 20 ml phosphate buffered saline (PBS) and extensively dialysed as described by Kedar and Bonavida¹⁰. For neat (N) HRSZ, zymosan (10 mg) was incubated with 1 ml of HRSA for 45 min at 37°C, washed twice and resuspended in 1 ml of PBS at pH 7.2. Dilutions of HRSA from 1 in 20 to 1 in 100 were also incubated with 10 mg of zymosan and similarly incubated and washed. For HRSA alone, zymosan was omitted; for RSAZ, histamine and ECDI were omitted and histamine was omitted in the preparation of RSAZ_{ECDI}. Serum treated zymosan (STZ) was prepared by incubating 1 ml fresh guinea pig serum with 10 mg zymosan and incubating and washing as for HRSZ. Hm, histamine dihydrochloride (10^{-3} mol l^{-1}), Z, zymosan (10 mg in 1 ml PBS). When unstimulated cells or cells with treatments were incubated in the presence of superoxide dismutase, values obtained were less than 2.00. Each test was performed in duplicate and the results represent the mean $\pm$ 1 s.e.m. of four experiments.

and particulate, many of which bind to the plasma membrane (for example, particles opsonised with complement⁴) through cell surface receptors. This suggests that there may be a close association between 'membrane recognition' of certain exogenous stimuli and the enzyme which initiates the primary oxygen-consuming reaction (also thought to be membrane bound and probably 'NADPH oxidase'⁵). In the experiments reported here superoxide anion formation (O_2^-) and chemiluminescence have been measured as these are recognised features of the respiratory burst of phagocytic cells⁵.

O_2^- generation by alveolar macrophages was measured by dismutase-inhibitable cytochrome *c* reduction. When histamine in free solution was incubated with purified alveolar macrophages, free of other phagocytic cells, the amounts of O_2^- formed were no more than those obtained with resting (unstimulated) cells. In contrast, when histamine was bound to particles such as zymosan (a yeast cell-wall extract) large amounts of O_2^- were generated. The binding of histamine (H) was achieved by first coupling the amine to rabbit serum albumin (RSA) (see Fig. 1) and then allowing this HRSA conjugate to adsorb on to the particle. Histamine coupled in this way is known not to be substantially altered chemically⁶. Also, we were able to show that bound histamine retained its biological activity in terms of its capacity to contract the isolated guinea pig ileum. The results shown in Fig. 1 were with zymosan although several other particles which absorbed the coupled histamine also generated O_2^- . These included a cross-linked dextrose gel (Sephadex G-10), a bead-formed agarose gel (Sephacrose 4B), a cross-linked polystyrene polymer (Amberlite XAD-2) and latex (polystyrene) beads. By themselves, or following addition of RSA alone, these particles did not generate appreciable amounts of O_2^- , indicating that the observed effect was independent of the chemical properties of the carrier and was a result of the histamine conjugated to RSA. The O_2^- formed was directly proportional to the quantities of HRSA offered to the particles (Fig. 1). Zymosan which had adsorbed a 1 in 20 dilution of HRSA generated as much O_2^- as zymosan incubated with fresh serum. Serum (as a source of complement) coated zymosan (STZ) is known to be particularly effective in initiating the respiratory burst in many phagocytic cells, including the alveolar macrophage⁷. When alveolar macrophages were incubated with the various controls shown in Fig. 1, the amount of O_2^- generated was similar to that in unstimulated cells. These results indicate that the observed effect was attributable to bound histamine and not to the zymosan alone or zymosan coated with the carrier protein in the presence (RSAZ_{BCDI}) or absence (RSAZ) of the coupling reagent (1-ethyl-3-(3-dimethylaminopropyl) carbodiimide). Of these controls RSAZ_{BCDI} gave the highest values but this was not significantly different from RSAZ, HRSA, Hm or Z.

Fig. 2 The time course of generation of O_2^- by alveolar macrophages activated with histamine bound to zymosan (HRSAZ). STZ (○), HRSAZ (●), RSAZ (△), HRSA (▲) and Hm (■) (10^{-3} mol l⁻¹) were prepared as in Fig. 1. □, unstimulated (resting) cells. Each time point was performed in duplicate and results represent the mean $\pm$ s.e.m. of four experiments.

Fig. 3 Chemiluminescence by alveolar macrophages activated with histamine bound to zymosan (HRSAZ). HRSAZ (0.1 ml) was incubated with 0.5 ml of 0.2 mM solution of luminol (Sigma) dissolved as described¹¹, and contained in BSS⁺⁺. Two million alveolar macrophages contained in 0.4 ml were added to this mixture and the counting commenced immediately. Experiments were performed in polypropylene minivials (Searle) contained in glass scintillation vials with pre-bored screwcaps (Koch-Light) which were pre-heated at 37 °C for 13 h. All manipulations were performed in the dark at 37 °C. Counts were recorded at room temperature in a Beckman LS-250 liquid scintillation counter, operating in the 'out of coincidence' mode¹², using a minimal iso-set module adjusted to detect approximately the lower third of the tritium energy spectrum. The counting mode was set to record infinite sequential, 0.2 min total count readings at a present error of 0.2%. HRSAZ dilutions: a 1:10; b, 1:20; c, 1:40; d, 1:80. The figure is representative of six experiments. Peak luminescence with the controls, HRSAZ+superoxide dismutase, RSAZ_{BCDI}, RSAZ, HRSA, RSA, Z, Hm (10^{-3} mol l⁻¹) and unstimulated gave values <73 c.p.m. $\times 10^3$. STZ gave peak luminescence of 617 c.p.m. $\times 10^3$.

The time course of O_2^- production by alveolar macrophages stimulated with histamine bound to zymosan by the RSA conjugate (HRSAZ) is shown in Fig. 2. This was compared with STZ, RSAZ, free histamine, the histamine conjugate in the absence of particles (HRSA) and the amounts formed by unstimulated macrophages. Maximal O_2^- generation with HRSAZ and STZ was achieved within 30 min whereas with RSAZ and HRSA the amounts detected were much less and did not 'plateau', even after 1 h. The relative differences between O_2^- produced by alveolar macrophages following activation by the various agents and the amounts produced by unstimulated cells were similar to those obtained in Fig. 1. These experiments (Figs 1 and 2) indicate that bound histamine is comparable to bound complement in its capacity to initiate the respiratory burst in alveolar macrophages and that the effects are both dose- and time-dependent.

We were also able to show that O_2^- production by bound histamine was an H_1 - and not an H_2 -receptor dependent effect. This was determined in seven experiments in which the alveolar macrophages were preincubated for 30 min with the appropriate drugs at various dilutions. The H_2 -receptor antagonists, burimamide and metiamide, at doses of 5×10^{-5} , 2×10^{-5} and 0.8×10^{-5} mol l⁻¹, produced insignificant inhibition of O_2^- production, the values being $8.3\% \pm 3.0$, $9.5\% \pm 2.9$, $10.5\% \pm 3.8$, and $3.4\% \pm 1.7$, $2.2\% \pm 1.6$, $8.4\% \pm 4.3$, respectively. In contrast, the H_1 -antagonists, chlorpheniramine and mepyramine at the same concentrations, gave linear dose-dependent inhibitions of $22.3\% \pm 3.8$, $13.8\% \pm 3.6$, $10.7\% \pm 4.4$ and $24.4\% \pm 5.0$, $19\% \pm 4.8$, $12.8\% \pm 3.3$, respectively. The inhibition produced by the highest doses of the H_1 -receptor antagonists were highly statistically significant ($P < 0.005$). The drugs had no significant effect on the resting values of O_2^- production or on O_2^- generated by STZ indicating that HRSAZ probably initiates the respiratory burst by the H_1 -dependent histamine receptor that we previously described using the 'rosette technique'¹.

Chemiluminescence, which also accompanies the respiratory burst of phagocytic cells⁵, was initiated by histamine bound to zymosan. As shown in Fig. 3 this effect was both time- and dose-dependent. This experiment was repeated five times and gave similar results. Chemiluminescence induced by HRSAZ or STZ was completely inhibited by superoxide dismutase indicating that light emission by these cells was closely associated with O_2^- production.

These results suggest that there may be a direct relationship between histamine and lung macrophages. We have established that histamine, when bound to a number of different particles, initiated the respiratory burst in these cells. The response, like the 'histamine rosettes' described previously¹, was H_1 -receptor dependent.

Although histamine alone was without effect it is known to bind to a number of plasma proteins ('histaminopexy'⁶) and so our observation may be of significance both physiologically, in the regulation of oxygen-dependent microbial killing by lung macrophages, and in disease states such as asthma and chronic bronchitis^{2,3}. In these latter situations high sputum concentrations of histamine may adversely influence the well recognised defensive role of the alveolar macrophage and so contribute to respiratory infections.

Anti-inflammatory steroids induce biosynthesis of a phospholipase A_2 inhibitor which prevents prostaglandin generation

ASPIRIN prevents prostaglandin (PG) generation by directly inhibiting the cyclo-oxygenase enzyme responsible for PG biosynthesis¹⁻³. In addition, there is now conclusive evidence that anti-inflammatory steroids can also prevent PG generation⁴⁻¹³. Unlike the aspirin-like drugs, steroids have no anti-cyclo-oxygenase activity but exert their action by preventing the release from phospholipids of the fatty acid substrates required for PG biosynthesis^{4-9,12,13}. We have shown that stimulation of thromboxane A_2 (TXA₂) release by agents such as histamine, 5-hydroxytryptamine and rabbit aorta contracting substance-releasing factor (RCS-RF) (but not arachidonic acid) is inhibited

Fig. 1 Male guinea pigs (250-300 g) were killed by cervical dislocation and exsanguination, and lungs were removed and washed in ice-cold saline and then homogenised in 10 ml Tris buffer (pH 7.5, 20 mM containing 2 mM $CaCl_2$, 1 mM Na_2MoO_4 and 1 mM $MgCl_2$). The homogenate was centrifuged at 100,000 g for 90 min at 2 °C. The supernatant was retained on ice until use, (usually within 2-3 h of preparation). Protein content was estimated by the Biuret method. The binding assay used reaction sets of 0.1 ml Tris buffer (20 mM pH 7.5), 0.3 ml cytoplasmic fraction, 0.05 ml unlabelled steroid or saline control and 0.05 ml ^3H -dexamethasone, incubated for 2 h at 4 °C. Unbound dexamethasone was adsorbed by adding acid-washed Norit charcoal (5 mg) and vortex mixing for 20 s. Charcoal was removed by centrifugation (10,000 g for 10 min). Supernatant (0.3 ml) was removed for estimation of bound dexamethasone using liquid scintillation counting. **a**, Total binding of dexamethasone by lung supernatant as a function of time. ^3H -dexamethasone (20 pmol) was used for this experiment; binding was maximal by 90 min, also shown as the uptake in the presence of 10^{-5} M unlabelled dexamethasone. **b**, Total binding of dexamethasone by lung supernatant (ordinate) as a function of the free steroid (abscissa). Curves represent one of four experiments. Binding varied between lungs, and although results were clear at <300 nM dexamethasone, the binding above this concentration became erratic and difficult to reproduce. The 'control' curve is derived from samples containing only ^3H -dexamethasone. The ^3H background curve is derived from samples containing no cytoplasmic protein. The other curves show displacement of the ^3H -dexamethasone from the receptor by cortisone (10^{-5} M) and 10^{-5} M unlabelled dexamethasone; this concentration gave a maximal displacement of the labelled drug. The protein concentration was 6.2 mg ml⁻¹. **c**, 'Specific' binding of dexamethasone is defined here as that binding resistant to the addition of 10^{-5} M unlabelled drug, and is calculated by subtracting the binding in the presence of 10^{-5} M dexamethasone from the binding found in its absence. Figures are expressed as fmol dexamethasone bound per mg cytoplasmic protein. Also shown is the displacement of the binding curve by 10^{-7} M dexamethasone, 10^{-6} M hydrocortisone and 10^{-5} M cortisone. Results are calculated from an experiment similar to that shown in **b**. The binding varied between experiments and a range of 100-400 fmol dexamethasone per mg cytoplasmic protein was observed in the four experiments carried out. ●, Control; ■, dexamethasone; △, cortisone; ○, hydrocortisone; ♦, ^3H background.

by anti-inflammatory steroids, and that their potency in this action closely parallels their anti-inflammatory activity^{12,13}. Furthermore, their mechanism of action involves the inhibition of phospholipase A_2 activity, and thus of arachidonate release within the lung^{12,13}. In several other tissues, the mechanism of steroid hormone action depends on the combination of the

steroid with a cytosolic receptor protein, the translocation of this drug-receptor complex to the nucleus and the initiation of protein biosynthesis¹⁴⁻¹⁶. We now show that similar events occur in the guinea pig perfused lung before inhibition by steroids of phospholipase A₂ activity (and thus TXA₂ generation). We have discovered a steroid-induced factor which mimics the anti-phospholipase effects of these anti-inflammatory agents.

Dexamethasone was used for most of the experiments, although results were confirmed with triamcinolone and hydrocortisone. Dexamethasone was used because it is a potent inhibitor, available as the soluble sodium phosphate salt (Decadron, Merck), and can be obtained in labelled form ([1,2(n)³H]dexamethasone, 39 Ci mmol⁻¹, Radiochemical Centre). We used this tritiated steroid to look for a steroid receptor protein in lung cells. The method was that of Baxter and Tomkins¹⁷ (see Fig. 1) which shows that there is a time-dependent, saturable 'specific' binding of labelled dexamethasone by the crude cytosol fraction of lung homogenate. This binding was reduced or prevented by unlabelled dexamethasone (10⁻⁷-10⁻⁵ M), higher concentrations (10⁻⁶-10⁻⁴ M) of the weaker anti-inflammatory steroid hydrocortisone, or by the 'anti-glucocorticoid' corticosterone (10⁻⁶-10⁻⁵ M), which binds to other steroid receptors¹⁸. The binding capacity of the cytosolic supernatant was abolished by pretreatment with papain (100 µg ml⁻¹ protein), or by heating the preparation to 40 °C for 60 min. The bound steroid could be removed from the binding protein by vigorous shaking with *n*-heptane. The radioactivity thus liberated co-chromatographed with authentic dexamethasone on TLC (developing solvent, chloroform:methanol:water, 9:1:0.1, v/v), indicating that no metabolism of dexamethasone had occurred. These results show that dexamethasone is bound to a receptor protein in one or more cell types in the lung.

In the second series of experiments, we investigated the activity of actinomycin D (an inhibitor of RNA but not protein biosynthesis)¹⁹, cycloheximide (an inhibitor of protein and RNA biosynthesis)²⁰ and puromycin (an inhibitor of protein biosynthesis)²⁰ on the steroid-induced suppression of phospholipase activity. Guinea pig isolated lungs were prepared²¹, and perfused with oxygenated Krebs' solution (37 °C) at 10 ml min⁻¹. First, we measured the release from the perfused lung of TXA₂ in response to stimuli (such as RCS-RF) which act through phospholipase activation¹². TXA₂ release was detected by a superfused rabbit aortic strip, and the TXA₂ generated by a standard stimulus was compared with that produced when a known amount of sodium arachidonate was injected through the lung. Infusion of steroids through the lung selectively abolishes stimuli which act through phospholipase activation without affecting arachidonate stimulation. Thus, the ratio between the two responses is a measure of phospholipase activity^{12,13}.

Second¹³, a specifically labelled phospholipid (2-[³H]-oleoyl]phosphatidylcholine) was injected through the lung (with a small amount of [¹⁴C]-oleic acid to act as an internal standard). Free oleic acid liberated by the action of phospholipase A₂ within the pulmonary vascular bed is measured by liquid scintillation counting of the extracted effluent. The hydrolysis of this phospholipid is suppressed by steroids and the results closely parallel those obtained by bioassay^{12,13}. Figure 2a shows that in the untreated lungs, dexamethasone (1 µg ml⁻¹) markedly reduced phospholipase activity as estimated by the release of TXA₂ or by hydrolysis of the radioactive phosphatide. This inhibition was reversed after the steroid infusion was discontinued, and responses had fully recovered after 1 h (not shown). Figure 2b-d shows that cycloheximide (2 µg ml⁻¹), actinomycin (1 µg ml⁻¹) or puromycin (5 µg ml⁻¹) either abolished or reduced the inhibitory effect of the steroid. Indeed, a potentiation of phospholipase activity was sometimes detected. The blockade of the inhibitory activity of steroid by inhibitors of RNA or protein synthesis implies that the action of the steroids depends on a transcriptional as well as a translational step. Cycloheximide pretreatment of the lung did not diminish the number of steroid receptors in cytosolic preparations.

Having demonstrated that corticosterone displaced dexamethasone from the cytoplasmic receptor, we tested its effect in an intact perfused lung. Corticosterone (25 µg ml⁻¹) given with or during an infusion of dexamethasone (1 µg ml⁻¹) reduced the inhibitory effect of the latter on phospholipase activity (as estimated on both biological and radiochemical assays) by up to 85%. Corticosterone itself had no intrinsic activity at these concentrations.

Fig. 2 The effect of dexamethasone (1 µg ml⁻¹) on lung phospholipase activity and the release of TXA₂, and the abolition of this action by protein and RNA synthesis inhibitors. The guinea pig isolated perfused lungs were prepared, and the bio- and radioassays carried out as described^{12,13}. All data have been reduced to the same format and are expressed as a per cent change from the control response. For the bioassay the anti-phospholipase activity was calculated as a decrease in the ratio between the release of TXA₂ by a standard dose of RCS-RF and a standard dose of arachidonic acid. Phospholipase activity is expressed as the per cent change in hydrolysis (pmol oleic acid released) occurring on injection through the lung. The data shown here represent one of 3-5 experiments. Protein and RNA synthesis was estimated by infusing 0.150 µCi [¹⁴C]-lysine or 12.0 µCi [³H]-uridine into a perfused lung over 1 h. Some lungs received saline only, others actinomycin (1 µg ml⁻¹), cycloheximide (2 µg ml⁻¹) or puromycin (5 µg ml⁻¹). After 1 h the lung was chopped with scissors and homogenized in a glass homogenizer. The proteins and nucleic acids were precipitated with 5 vol ice-cold 1 M perchloric acid and the precipitate was sedimented in a centrifuge. This precipitate was washed twice more with 5 vol 0.5 M perchloric acid and the precipitate was sedimented in a centrifuge. This precipitate was then washed with 5 vol ethanol:ether (1:1) and the final pellet solubilized with concentrated NaOH. The radioactivity was estimated by liquid scintillation counting after neutralization with acetic acid, and the protein content was estimated by the Biuret reaction. Results are expressed as per cent changes from control d.p.m. per mg protein. a, Control; b, + 2 µg ml⁻¹ cycloheximide; c, + 1 µg ml⁻¹ actinomycin; d, + 5 µg ml⁻¹ puromycin.

Clearly, steroids act in the perfused lungs in much the same way as they act to produce metabolic effects in other tissues. Could this effect be produced by stimulating the biosynthesis of an inhibitory factor, perhaps a polypeptide? We have now demonstrated the presence of such a factor using perfused, cycloheximide-treated lungs which are thus resistant to the inhibitory action of steroids. First, effluent from a perfused lung (generator lung) was re-oxygenated and pumped directly through another perfused lung (test lung) which also received

cycloheximide ($2 \mu\text{g ml}^{-1}$) to render it insensitive to steroids. Anti-inflammatory steroids were infused either through the generator lung (TL) or into the effluent leaving the generator lung (IE). Thus, the only difference in the effluent perfusing the test lung was whether or not the steroid had passed through the first lung. Bioassay or radiochemical assays were as described earlier.

When steroids were infused into the test lung (Fig. 3) they did not affect phospholipase activity. When steroids were infused into the generator lung, however, phospholipase activity of the test lung (estimated by either technique) was greatly reduced. Similar results were obtained when the steroids were perfused TL first and then changed to IE. In this case the depressed phospholipid hydrolysis and responses to RCS-RF returned when the steroids were infused IE.

Second, two lungs were perfused simultaneously, one received steroid TL the other IE. The only difference in the perfusates was that in one case the steroid had perfused through the lung and in the other it had gone directly into the effluent. After storage at 4°C overnight or for longer periods of time, the flasks of effluent were re-oxygenated and alternately perfused through a lung receiving cycloheximide. Some results obtained with this technique are shown in Fig. 4. When perfused with fresh Krebs' solution, or the effluent containing steroid-infused IE, there was no inhibition of phospholipase activity, but when perfused with effluent from steroid-treated lungs the basal phospholipid hydrolysis was depressed or abolished and the responses to RCS-RF attenuated. Return to normal occurred when the steroid was omitted from the ordinary Krebs' solution or when effluent was used from lungs where steroids were infused IE.

No metabolism of dexamethasone occurred in the lungs, as infusing the tritiated drug, extracting it from the Krebs' solution with *n*-heptane and analysing the product by TLC showed that all the radioactivity co-chromatographed with authentic dexamethasone. Triamcinolone acetonide and hydrocortisone hemisuccinate gave similar effects.

We conclude that the anti-phospholipase action of steroids is induced by a mechanism essentially similar to that mediating their other metabolic actions. First, the steroid combines with a receptor located in the cell cytoplasm of one or more cell types in the lung. The amounts of steroid required to saturate the receptors in the lung (10–20 pmol per mg protein) are higher than those reported for some other tissues (see refs 17, 22), and

Fig. 3 A factor induced by steroids is released into the effluent of the lung and can have an anti-phospholipase effect in a second lung. Two lungs were perfused in series as shown. The re-oxygenated effluent from the 'generator lung' was pumped into the test lung which also received cycloheximide ($2 \mu\text{g ml}^{-1}$) to prevent the action of steroids. Dexamethasone ($1 \mu\text{g ml}^{-1}$) was infused either directly into the effluent from the first lung (IE) or first through the generator lung (TL). During the equilibration period the steroid was infused IE and there was no change in the activity of the enzyme; however, when infused TL there was an immediate fall in phospholipase activity of the second lung showing that a factor was formed in the first lung which had an anti-phospholipase effect in the second. When the steroid was again perfused IE the phospholipase activity returned to control values. Similar results were obtained in five other experiments. $\square$, Bioassay; $\blacksquare$, radioassay.

Fig. 4 Steroids induce the biosynthesis of a stable anti-phospholipase factor. The assay was with a single perfused lung receiving cycloheximide ($2 \mu\text{g ml}^{-1}$) to prevent the action of steroids. The lung is perfused with one of three batches of Krebs' solution: a, normal Krebs' solution, b, the lung effluent to which dexamethasone ($1 \mu\text{g ml}^{-1}$) had been added, c, the effluent from a lung in which dexamethasone ($1 \mu\text{g ml}^{-1}$) had passed through the lung. Only during an infusion of solution c was there a fall in the phospholipase activity of the recipient lung. The steroid-induced factor was stable in Krebs' solution at 4°C for at least 7 but less than 14 d. $\square$, Bioassay, $\blacksquare$, radioassay.

the actual binding (fmol per mg protein) is much less. Perhaps there are more receptors per mg lung protein, or they have a much lower affinity than those of other tissues studied. Scatchard plots of the binding data were non-linear, perhaps indicating the presence of more than one receptor population. Certainly, combination with the receptor is important for the action of steroids, as cortisone displaced labelled dexamethasone from the receptor and blocked the inhibitory action of this steroid in the perfused lung system. Combination of cortisone with the steroid receptor may form an inactive complex¹⁸.

Our experiments do not show whether combination of the steroid with the receptor is followed by translocation of this complex to the nucleus. However, the subsequent genetic expression does occur in lung tissue and this involves transcription as well as translation, for inhibitors of RNA as well as of protein biosynthesis block the steroid effect. The disparity of chemical structure and site of action suggests that these inhibitors exert their effect in this system by an action on the RNA/protein synthetic machinery. Interestingly, actinomycin D blocks the anti-inflammatory effect of steroids *in vivo*²³. (During preparation of this paper, Danon and Assouline²⁴ reported findings similar to some of ours in rat renal papillary tissue.)

Clearly, in perfused lungs, steroids induce the synthesis of a factor which blocks phospholipase A_2 and this factor can be transferred from one perfused lung to another. Presumably, it is a peptide or protein, as its biosynthesis is prevented by cycloheximide. The biosynthesis of this factor may be crucial to the anti-inflammatory effect of steroids. We have observed the close relationship between the anti-phospholipase activity and the anti-inflammatory activity of corticosteroids¹². There is considerable evidence linking the generation of prostaglandins with inflammation, pain and fever (see ref. 25), and several other products of fatty acid oxidation such as 12-hydroxy-5,8,14-eicosatetraenoic acid²⁶ or malondialdehyde²⁷ could also be pro-inflammatory or cytotoxic. Furthermore, slow-reacting substance A may be derived from arachidonic acid^{28,29}. The non-steroid aspirin-like drugs block the generation of cyclooxygenase products^{1,30} but because the substrate fatty acids are rate limiting (see refs 12, 13), the anti-inflammatory steroids can prevent the biosynthesis of a whole cascade of lipid mediators, so that the steroid-induced anti-phospholipase factor could be important in controlling the inflammatory response. If this is so, steroids would not have an anti-phospholipase effect in cells which do not contain steroid receptors.

Our discovery that the action of steroids in this tissue depends on the continued biosynthesis of protein and RNA also means

that these drugs do not exert their effect by 'membrane stabilisation'. We do not yet understand how the steroid-induced factor inhibits the phospholipase and what (if any) other pharmacological actions this factor has. Some phospholipases require 'activation' before catalysis can proceed; in some cases this involves the removal of a peptide protecting the active centre³¹. One effect of the steroid-induced factor could be to mimic the action of this peptide. Whatever the mechanism of action, the discovery that the anti-phospholipase activity of steroids is mediated by a soluble 'second messenger' is likely to contribute to the understanding of the anti-inflammatory action of these drugs.

Stimulatory effect of vanadate on (Na⁺ + K⁺)-ATPase activity and on ³H-ouabain-binding in a cat heart cell membrane preparation

VANADATE has been reported to inhibit (Na⁺ + K⁺)-ATPase activity in membrane preparations from dog kidney¹ and in red cells². This inhibition, which occurs in the nanomolar concentration range in the presence of high Mg²⁺ concentrations and in the micromolar range at physiological Mg²⁺ concentrations^{2,3} is specific as other ATPase enzymes are not affected in these conditions¹. Therefore vanadate has been suggested to be 'an ideal specific regulator' of (Na⁺ + K⁺)-ATPase¹. We have shown⁴ that vanadate has a distinct positive inotropic effect in cat papillary muscle. It has been claimed that the positive inotropic action of cardiac glycosides, which are specific inhibitors of (Na⁺ + K⁺)-ATPase activity^{5,6}, is associated with the

inhibition of that enzyme. If that is so, vanadate would be expected to inhibit (Na⁺ + K⁺)-ATPase, in a concentration-dependent manner, in parallel with its effect on force of contraction. To test this hypothesis, we measured the effect of vanadate on (Na⁺ + K⁺)-ATPase activities and on ³H-ouabain-binding in identical conditions in a membrane preparation taken from cat hearts that were also used for experiments on contraction. We report here, however, that vanadate may stimulate (Na⁺ + K⁺)-ATPase activity transiently and ³H-ouabain-binding permanently in these conditions.

After the papillary muscles had been dissected from the cat hearts⁴, remaining ventricular tissue was frozen quickly and kept at -60 °C for up to 4 weeks until further use. After thawing, (Na⁺ + K⁺)-ATPase (EC 3.6.1.3.) was prepared from 12 hearts as described by Pitts and Schwartz⁷ but without glycerol treatment. Enzyme activity was determined by the coupled optical assay in an ATP-regenerating system⁸. It was measured as 0.32 U mg⁻¹ membrane protein; 97% of total ATPase activity could be inhibited by ouabain (10⁻⁴ M). One enzyme unit is defined as 1 μmol ATP hydrolysed per min at 37 °C. Protein was determined by the method of Lowry *et al.*⁹.

Fig. 1 Stimulatory and inhibitory effect of vanadate on (Na⁺ + K⁺)-ATPase activity. Compounds were dissolved in H₂O daily. Incubation medium was the same as that used for the determination of force of contraction⁴ and contained (mM): NaCl, 136.9; KCl, 5.4; CaCl₂, 1.8; MgCl₂, 1.05; NaH₂PO₄, 0.42; glucose, 5.5 (buffered with NaHCO₃ to pH 7.4); total volume was 2 ml. Enzyme protein (1 mg) was incubated in this medium for 120 min at 37 °C in each test tube with different concentrations of NH₄VO₃ (Merck, Darmstadt). Then 0.2 ml of this mixture was assayed rapidly for ATPase activity in the coupled optical assay⁸, followed by continuous recording photometrically for 20 min at least. The time of addition of NH₄VO₃ is marked by arrows.

The effects of NH₄VO₃ on (Na⁺ + K⁺)-ATPase activity were measured as described in the legend to Fig. 1. A typical photometric recording is shown in Fig. 1. Enzyme activity is followed continuously by the degradation of NADH at 334 nm. The disappearance of NADH is related stoichiometrically to the hydrolysis of ATP in the coupled optical assay⁸. Soon after addition, NH₄VO₃ in a final concentration of 25 μM inhibited (Na⁺ + K⁺)-ATPase about 65%. Higher concentrations initially inhibited the enzyme appreciably less (100 μM) or even stimulated it above control values for several minutes. We refer to this as 'transient initial stimulation'. For instance, 500 μM stimulated the enzyme 180% for about 3 min (Fig. 2). But after about 5 min it caused progressive inhibition. This rather strange effect

Fig. 2 Concentration-dependent effect of vanadate on $(\text{Na}^+ + \text{K}^+)\text{-ATPase}$ activity. Cat heart ventricular cell membranes (1 mg protein) were preincubated for 120 min in medium, as described in the legend to Fig. 1, to which was added increasingly large amounts of NH_4VO_3 , total volume 2 ml each. After 120 min, 0.2 ml of this medium containing enzyme protein was assayed rapidly for ATPase activity in the coupled optical assay with an ATP-regenerating system⁸ at the same vanadate concentrations as during preincubation. ●, The highest initial ATPase activity, measured usually after 3 min (Fig. 1); ○, The lowest activity measured within 20 min. Vanadate concentrations above 30 μM cause an initial transient stimulation, followed by inhibition. Similar results were obtained in three other experiments.

was not due to the action of NH_4VO_3 on the enzymatic reaction in the coupled optical assay (phosphoenolpyruvate, pyruvate kinase, lactic dehydrogenase, NADH) because the incubation medium alone (without $(\text{Na}^+ + \text{K}^+)\text{-ATPase}$ -containing cell membranes), or with heat-denatured cardiac cell membranes, did not respond in this way to the addition of NH_4VO_3 in the respective concentrations.

In a second set of experiments cat heart ventricular membranes were preincubated for 120 min in the same incubation medium used for the determination of force of contraction in the cat papillary muscles⁴ (as described above), with and without increasingly large concentrations of NH_4VO_3 (0.005–2.500 μM) at 37 °C. After 120 min an aliquot of membranes was assayed for $(\text{Na}^+ + \text{K}^+)\text{-ATPase}$ activity by the coupled optical assay⁸ (Fig. 2). The results reveal a concentration-dependent inhibition of $(\text{Na}^+ + \text{K}^+)\text{-ATPase}$ activity up to 25 μM NH_4VO_3 , half-maximal at 5 μM . An initial transient stimulation was seen at the same concentrations as in the absence of preincubation, starting at 50 μM and becoming maximal at 500–1,000 μM . Further experiments showed that preincubation had no effect unless ATP was present, thus suggesting that vanadate is bound

Fig. 3 Time course of the positive inotropic effect of 100 μM NH_4VO_3 in an electrically driven cat papillary muscle, mounted for the recording of isometric contractions, as described previously⁴. NH_4VO_3 was added at zero time and was present throughout the experiment. Frequency of stimulation, 0.2 Hz; temperature, 35 °C, extracellular Ca^{2+} concentration, 1.8 mM; preparation diameter 0.8 mm.

by $(\text{Na}^+ + \text{K}^+)\text{-ATPase}$ only if it is enzymatically active. This agrees well with the demonstration by Cantley *et al.*³ that vanadate exerts its effect at the inner side of the erythrocyte cell membrane, where the enzymatically active site is said to be located⁶.

$(\text{Na}^+ + \text{K}^+)\text{-ATPase}$ activity was stimulated again by 50 μM NH_4VO_3 , reaching maximal stimulation at 500–1,000 μM . Previous experiments have demonstrated the positive inotropic effect in the same concentration range⁴. Thus, there was a correlation between the transient stimulatory effect of vanadate on $(\text{Na}^+ + \text{K}^+)\text{-ATPase}$ activity and the positive inotropic effect when both experiments (that is with papillary muscles and with membrane preparation) involved tissue from the same heart assayed in identical media. Such a correlation did not apply to the inhibitory effect of vanadate.

Fig. 4 Effect of vanadate on ^3H -ouabain-binding to cat cardiac cell membranes. Cat heart ventricular cell membranes (0.17 mg protein) were incubated for 120 min in medium, as described in the legend to Fig. 1, to which was added 3 mM ATP (Boehringer, Mannheim), 6 p mol ^3H -ouabain (specific activity 14.4 Ci mmol⁻¹, lot no. 500-183, New England Nuclear, Dreichenheim) and the indicated concentrations of NH_4VO_3 . ^3H -ouabain bound to the membranes was determined after rapid filtration (Whatman GF/C glassfibre filters). The radioactivity on the filters was determined by liquid scintillation counting¹⁰. Unspecific binding of ^3H -ouabain to the membranes was determined after addition of unlabelled 10^{-4} M ouabain. It was always less than 3% of total ^3H -ouabain-binding and was subtracted from the amount of total bound radioactivity. Similar results were obtained in two other experiments.

The reasons for the apparent discrepancy between our results and reports that vanadate exclusively inhibits $(\text{Na}^+ + \text{K}^+)\text{-ATPase}$ from various sources may be either the use of the phosphate determination method^{1,2,11} (which does not facilitate continuous monitoring of the hydrolysis of ATP) or the determination of enzyme activity by the coupled optical assay after equilibrium had been established ('after... the time curve became linear')³. It is possible that the initial transient stimulation of $(\text{Na}^+ + \text{K}^+)\text{-ATPase}$ activity by vanadate has been overlooked by other investigators. This effect was not unique to the cat heart enzyme, however. Similar results were obtained with $(\text{Na}^+ + \text{K}^+)\text{-ATPase}$ preparations from horse and human hearts (not shown). Furthermore, in accordance with previous reports³, the concentrations of vanadate needed to inhibit the enzyme were much lower in the presence of high concentrations of Mg^{2+} (10 or 20 mM). NH_4Cl alone did not affect ATPase activity in the conditions used. Further addition of 20 mM NH_4Cl caused no measurable change in the effects of vanadate on enzyme activity. Results were the same with NH_4VO_3 or Na_3VO_4 , which had the same positive inotropic action.

The biological significance of the transient stimulatory and steady-state inhibitory effects of vanadate on $(\text{Na}^+ + \text{K}^+)\text{-ATPase}$ activity is not clear. Transient stimulation occurred at

the same concentration range as did the inotropic effects⁴. Both began rather rapidly (1–2 min) after the application of NH_4VO_3 , but the former lasted only for a few minutes, whereas the latter remained virtually stable for at least 30 min, which was the longest time investigated (Fig. 3). Perhaps the stimulatory effect triggers the inotropic effect. Of course both the stimulation and the inhibition of the enzyme might be an artefact due to the disruption of the cardiac cell membrane. However, the transient stimulatory effect of vanadate concentrations that also increase the force of contraction might be related to the reported stimulation of $(\text{Na}^+ + \text{K}^+)\text{-ATPase}$ by very low but positive inotropic concentrations of cardiac glycosides^{6,12,13}. That effect is controversial⁶, however, although recent studies have suggested stimulation of the active transmembranous transport of cations after addition of low but positive inotropic concentrations of cardiac glycosides^{14–16}.

It is well established that the enzyme protein containing $(\text{Na}^+ + \text{K}^+)\text{-ATPase}$ activity spans the cell membrane and specifically binds cardiac glycosides with high affinity on the outside of the cell membrane⁶. Cardiac glycosides supposedly exert their positive inotropic effect after binding to the enzyme^{6,17}. Thus, it seemed reasonable to examine the effect of vanadate on specific ^3H -ouabain-binding to $(\text{Na}^+ + \text{K}^+)\text{-ATPase}$ of the cat ventricular cell membrane preparation in the same conditions. Figure 4 shows that vanadate at concentrations greater than $0.5 \mu\text{M}$ stimulates ^3H -ouabain-binding in a concentration-dependent manner. Further experiments (not shown) demonstrated that this effect was due exclusively to an increased affinity of the binding sites for ouabain as the number of binding sites stayed constant. Cantley *et al.*^{3,18} have shown, however, that vanadate does not interact with ouabain-binding sites but rather with the ATP-binding sites of the enzyme at the inner side of the cell membrane. Thus the increased binding of ouabain to $(\text{Na}^+ + \text{K}^+)\text{-ATPase}$ seems to be an indirect effect of vanadate in certain conditions.

Thyrotropin-releasing hormone: central site of action in antagonism of pentobarbital narcosis

THYROTROPIN-RELEASING HORMONE (TRH) is capable of antagonising pentobarbital narcosis, and this effect is independent of its hypophysiotropic function^{1,2}. The potency of intraventricular injections^{2,3} and the localisation of TRH in nerve terminals from both hypothalamic and extrahypothalamic sites^{4,5}, suggest that TRH may function as a neuromodulator in the central nervous system (CNS)⁶. Although TRH antagonism of pentobarbital has been behaviourally and electroencephalographically^{7,8} characterised, the underlying neuroanatomical substrate remains unknown. In an attempt to identify the central substrate mediating this effect, we have used intracerebral microinjection of TRH into specific brain loci. Brain sites were chosen to represent large neuroanatomical regions—as cholinergic activation has been hypothesised to mediate pentobarbital antagonism by TRH, structures belonging to the cholinergic activating system⁹ were examined, and we also examined medially located brain regions that Wei *et al.*¹⁰ found to be most active at inducing TRH-mediated shaking. While a number of sites were found responsive at 500 ng of TRH, the septal region proved exceptionally sensitive by responding significantly at only 5.0 ng TRH.

Male Sprague-Dawley rats (230–330 g at the time of surgery) were individually housed under a 12-h light-dark cycle. The animal was allowed at least 7 days to recover, following surgery and a minimum of 5 days between administrations of drug. Using pentobarbital anaesthesia (50 mg per kg body weight intraperitoneally), each animal was bilaterally implanted with guide cannulas (26 gauge) in 2 or 19 brain loci (four cannulas per animal). Implantations were made to a depth of 1 mm above designated injection sites, and, where applicable angled to avoid ventricular penetration. Injections were made with a 33-gauge needle connected to a $1\text{-}\mu\text{l}$ Hamilton syringe by polyethylene tubing (PE-10). A small air bubble was introduced into the tubing to give a visible indication of fluid movement. Total injection volumes were $0.5 \mu\text{l}$ per hemisphere administered over a 30-s period, and 10 s were allowed to elapse before removal of the needle. Test animals were injected intraperitoneally with 40 mg per kg pentobarbital. At 20 min after loss of righting reflex, TRH (Abbott) dissolved in 0.9% saline, or an equal volume of saline alone, was bilaterally injected. After intracranial injection, the animal was placed on its side, and return of righting reflex recorded when the animal had righted itself three times in 60 s. Cannula location was verified histologically. Before intracardiac perfusion with 10% formalin,

Fig. 1 Dose-response curve for intraseptal TRH antagonism of pentobarbital narcosis. the number of animals tested at each dose is shown in each column. * $P < 0.001$ compared with septal saline, two-tailed Student *t*-test.

Table 1 Effect of intracerebral TRH on the duration of pentobarbital narcosis measured from loss of righting reflex

Brain region	Dose (μ g)	Stereotaxic coordinates (mm) [†]	Narcosis duration [‡] (min)

small lesion was placed 1 mm below each guide cannula by passing 1 mA of anodal current for 3 s. Brains were frozen, 50- μ m sections made at the lesion site, and sections stained with cresyl violet.

Doses of TRH for each site were chosen on the basis of preliminary data obtained using whole-brain doses of 500 ng. Sites not demonstrating a significant decrement in the duration of narcosis at 500 ng, as compared with animals receiving only pretreatment with 40 mg per kg pentobarbital, were further examined with 5- μ g doses of TRH. Even with 5 μ g of TRH several areas proved to be insensitive, including the amygdala, cerebellum, somatosensory cortex, caudate, lateral hypothalamus, and lateral preoptic area (P > 0.01) (Table 1). In contrast, the hippocampus and parafascicular nucleus did demonstrate TRH sensitivity to 5- μ g doses. However, considering the magnitude of the dosage and the proximity of these sites to the ventricular system and/or sites demonstrating TRH sensitivity at 500 ng, the possibility that TRH may be diffusing from the injection site to more sensitive areas should be considered. That many areas remained insensitive to TRH, even at a dose of 5 μ g, is in contrast to the results of Carino *et al.*¹¹ who found both the cortex and cerebellum of the rabbit to be sensitive to a dose of 1 μ g. A possible explanation for the differences observed might be that rabbits and rats respond differently. Alternatively, Carino *et al.* used injection volumes of

2 μ l, and diffusion of TRH to active sites could also be an explanation.

As in the investigation of TRH-induced shaking by Wei *et al.*¹⁰, we found that the more medially located brain regions were most sensitive to TRH antagonism of pentobarbital narcosis. The moderate sensitivity observed in the present study with the relatively lateral nucleus accumbens and substantia nigra is an exception. The most sensitive area was the septal region. The dose-response curve for TRH antagonism of pentobarbital narcosis in the septum demonstrates that significant antagonism occurred with a dose as low as 5.0 ng (Fig. 1). While several sites responded significantly at 500 ng TRH, when the five most sensitive areas, including the septum, medial preoptic area, mesencephalic periventricular grey (PVG), locus coeruleus, and medial thalamus, were examined at a dose of 10 ng, only the septum differed significantly from septal saline injections (P < 0.01). This finding indicates at least a twofold higher sensitivity of the septum over the next most sensitive areas and implicates it as the most important site of action in TRH antagonism of pentobarbital narcosis. This evidence of marked sensitivity is supported by numerous data, including immunohistochemical¹² and chromatographic¹³ identification of TRH in the septal region, the demonstration of calcium-dependent release of immunoreactive TRH from septal synaptosomes in the presence of elevated potassium concentrations¹⁴, and the demonstration by Winokur and Beckman¹⁵ that septal neurones respond to iontophoretic TRH. Furthermore, Burt (ref. 16 and personal communication) has found that the greatest concentration of high-affinity TRH-binding sites in calf and sheep extrahypothalamic brain tissue was located in the septum and nucleus accumbens.

TRH has often been associated with modulating cholinergic transmission. This is based on investigations indicating that anti-muscarinic compounds can effectively antagonise TRH-induced arousal of pentobarbital-narcotised animals¹, and studies by Yarbrough¹⁷ demonstrating TRH potentiation in the excitatory response of cortical neurones to iontophoretic acetylcholine (ACh). Moreover, it has long been known that pentobarbital increases cortical and hippocampal ACh levels¹⁸, and Schmidt¹⁹ has shown that TRH will reverse this effect of pentobarbital on ACh levels in both the hippocampus and cortex. The importance of the septum in central cholinergic pathways is demonstrated by the observation that this region is heavily stained for acetylcholinesterase⁹. In addition, there are many hippocampal afferents from the medial septum; and various lines of evidence²⁰ support the hypothesis that the septohippocampal pathway is cholinergic. Further, it has been demonstrated that electrical stimulation of the septum results in a marked increase in ACh output from both the hippocampus²¹ and cortex²². Therefore, in view of the present findings, activation of the septum by TRH is a possible mechanism mediating the decrease in hippocampal and cortical ACh levels reported by Schmidt in the pentobarbital-pretreated rat.

Thus the septum is highly sensitive to TRH when compared with other brain regions, but with systemic administration it is likely that TRH acts in part through less sensitive brain sites.

Corticotrophin releasing factor may be modulated vasopressin

CORTICOTROPHIN RELEASING FACTOR (CRF) was the first of the postulated hypothalamic factors controlling the release of hormones from the pituitary gland to be demonstrated biologically¹. However, it is extraordinary that after 24 years of research, techniques which have established the identity of the hypothalamic peptides involved in the release of thyrotrophin, the gonadotrophins and growth hormone, have been unsuccessful when applied to the search for a factor responsible for

Fig. 1 Chromatography of rat SME on BioGel P2 (200-400 mesh). Twenty rat stalk-median eminences (4 mg tissue wet weight per SME) were homogenised in 1.5 ml 10 mM HCl. After addition of NaCl (9 mg ml⁻¹) and centrifugation (3,000 g) the supernatant was applied to a column (1.5 × 50 cm) of BioGel P2 (200-400 mesh) equilibrated with 10 mM HCl containing NaCl (9 mg ml⁻¹) and ascorbic acid (1 mg ml⁻¹) at 4 °C. The column was eluted with the same buffer and hourly fractions (2.5 ml) were collected. Each fraction was neutralised with 25 µl 1.1 M NaHCO₃ and was diluted 1.5 in the appropriate assay buffer. *a*, ●, CRF bioactivity, as measured by output of immunoreactive ACTH from the cell column; ○, AVP immunoreactivity (ng ml⁻¹ in 1:5 dilution). *b*, ●, LHRH bioactivity as measured by output of immunoreactive LH from the cell column; ○, LHRH immunoreactivity (ng ml⁻¹ in 1:5 dilution). No significant amounts of ACTH or LH were detected in any of the fractions. V₀, void volume of column.

Fig. 2 Comparison of the CRF bioactivity of crude SME (one SME per ml: 1 ml contains neutralised acid extract prepared from the rat stalk-median eminence), synthetic AVP, and the 'AVP-CRF' peak shown in Fig. 1*a* (pooled fractions 43-51). These results were obtained from a chromatogram run in 10 mM HCl containing NaCl (9 mg ml⁻¹) without ascorbic acid. Doses were given randomly in triplicate and results represent mean ± s.e.m.

adrenocorticotrophin (ACTH) release^{2,3}. Vasopressin invariably releases ACTH from the anterior pituitary, but its partial agonistic properties *in vitro*⁴⁻⁶, its low potency *in vivo*⁷ and the isolation of active CRF fractions with little or no vasopressin activity^{2,3,8,9} have led to its rejection as a physiological CRF^{10,11}. However, recent immunological and immunocytochemical findings have led to renewed interest in the role of vasopressin in ACTH release. High concentrations of immunoreactive vasopressin have been found in portal blood and a direct vasopressin-neurophysin containing axonal pathway to the hypophyseal portal system, which seems to be under the influence of the adrenal cortex, has been identified^{12,13}. Using a sensitive releasing factor bioassay system, the perfused isolated anterior pituitary cell column¹⁴, and various immunological techniques, we have presented evidence to support the idea that vasopressin plays a major part in control of ACTH release⁶, and we now report the existence of hypothalamic factors with weak, labile CRF activity which potentiate the CRF activity of vasopressin to give it full agonistic properties indistinguishable from crude extracts of rat stalk median eminence (SME). Thus we propose that CRF is vasopressin modulated by other hypothalamic factor(s) released into the hypothalamo-hypophyseal portal system.

We reported previously that the immunological characteristics of the vasopressin-like material in rat SME were identical to synthetic arginine vasopressin (AVP) although the AVP content could never account for more than 30% of the biological activity of the extract⁶. The luteinising hormone releasing hormone (LHRH) bioactivity of SME, however, was completely in accord with its immunoreactive LHRH content. Surprisingly, when we attempted to remove the 'interfering' AVP from SME by preincubation with AVP antisera, the CRF activity was also specifically and totally quenched⁶.

The CRF biological activity of a crude extract of SME was fractionated by gel filtration (Fig. 1). The first small peak at the void volume (V₀) contained negligible CRF activity (Fig. 1*a*). The material in the second peak (fractions 22-28) appeared to be nonspecific (N₀) in the bioassay as it also released luteinising hormone (LH) (Fig. 1*b*). The major peak of CRF activity (fractions 39-53) eluted in the expected position for AVP and contained the peak of AVP immunoreactivity (Fig. 1*a*). The major peak of LHRH bioactivity coincided with the immunoreactive peak of LHRH (Fig. 1*b*). The log-dose response characteristics of the material in the 'AVP-CRF' peak (fractions 43-51) were indistinguishable from those of synthetic AVP, each was a partial agonist in the CRF bioassay when compared with SME (Fig. 2). Using three vasopressin antisera of differing specificities⁶, the vasopressin immunoreactivity of this peak was characterised as AVP.

Fig. 3 The synergistic effect of recombination of the CRF peaks in Fig. 1 and synthetic vasopressin. The results were obtained from a chromatogram run in 10 mM HCl containing NaCl (9 mg ml⁻¹) and ascorbic acid (1 mg ml⁻¹) at 4 °C. V₀, N₁ and 'AVP-CRF' are pooled fractions 11–31, 22–28 and 43–51, respectively, in Fig. 1.

Thus the material of the major CRF peak resembles synthetic vasopressin immunologically, chromatographically (on BioGel P2) and biologically (in our CRF bioassay) and the lack of full agonist bioactivity of 'AVP-CRF' suggests that chromatography has removed some synergistic factors.

The reappearance of biological activity after recombination of all the fractions after gel filtration of SME has been reported previously¹⁵, but in a recent review, Saffran and Schally³ reported that this work could not be repeated. Initially we failed to observe any potentiation when AVP was recombined with fractions from other areas of the chromatogram. However, when the chromatographic column was equilibrated and developed with eluant containing the antioxidant ascorbic acid, we consistently observed potentiation of the CRF bioactivity after recombination of the 'AVP-CRF' peak with other areas of the chromatogram. This potentiation was also observed with synthetic AVP. Figure 3b shows that the combined 'AVP-CRF', V₀ and N₁ fractions had bioassay log dose-response characteristics similar to those of crude SME. Equivalent quantities of synthetic AVP added to a mixture of V₀ and N₁ also gave a curve similar to that for SME (Fig. 3c). There was some slight synergism between V₀ and N₁ but this activity was unstable after storage for short periods at -20 °C. As crude extracts of normal SME are stable to storage and heat treatment⁶, it seems that AVP has a stabilising influence on the CRF activity of SME.

Studies with Brattleboro rats¹⁵, which are vasopressin deficient, have shown significantly reduced CRF bioactivity in their SME (20% of normal) which is unstable to storage at -20 °C, thus resembling the activity of V₀ and N₁ peaks of normal SME. Chromatography of Brattleboro SME yielded V₀ and N₁ peaks similar to those shown in Fig. 1 but the 'AVP-CRF' peak, with respect to both CRF bioactivity and AVP immunoactivity, was absent. The Brattleboro LHRH chromatogram was identical in all aspects to that for normal SME¹⁶.

We conclude that the CRF bioactivity of a crude stalk median eminence extract is due to a multi-factor system. Vasopressin is the major component whose potency is modulated by synergistic factors which have weak inherent CRF bioactivity. They lose most of their bioactivity and all of their ability to potentiate vasopressin when separated from it under non-reducing conditions as indicated by the negligible synergism of the components of the chromatogram when ascorbic acid is omitted. In view of the apparent compound nature of CRF bioactivity and the instability of some of its components, it is not surprising that the search for a pure peptide, distinct from vasopressin, with potent CRF activity has been unsuccessful.

This multi factor hypothesis is an attractive one because of the variety of stress situations (physiological, pathogenic, psychological), in addition to circadian rhythm, in which ACTH is secreted. Thus, the weak agonistic properties of vasopressin could be modulated by a specific factor or permutation of factors

in different situations. The factors, in turn, could be involved in the simultaneous release of growth hormone and/or prolactin, which are also released during stress.

Effect of electroconvulsive shock on monoaminergic receptor binding sites in rat brain

CHRONIC administration of either tricyclic antidepressant drugs or monoamine oxidase inhibitors, which are effective in the treatment of endogenous depression, has been shown to decrease the sensitivity of noradrenaline (NA)-stimulated adenylate cyclase^{1–5} and to decrease the apparent density of β -adrenergic receptor binding sites in rat brain^{6–10}. This alteration in receptor mechanisms by antidepressant drugs seems to be selective, as neither α -adrenergic nor serotonergic receptor binding in rat cortex is altered by the tricyclic drug desipramine⁷. It is therefore of interest to know whether other forms of antidepressant intervention alter receptor mechanisms in the brain and if so, whether they display a time course and selectivity similar to that of antidepressant drugs. Here, we have investigated the effects of a single and of multiple electroconvulsive shocks (ECS) on rat brain monoaminergic receptor binding sites and report that the density of β -adrenergic receptors is decreased.

Electroconvulsive shock (150 mA, 200 ms) was administered to male Sprague-Dawley rats through saline-moistened corneal electrodes. Controls were handled in the same manner except that no current was passed. Shocks were administered for 1 day and for 7 consecutive days. All shocked rats experienced generalised tonic-clonic seizures. Rats were decapitated 24 h after their last shock and the cortex and corpus striatum were dissected from the brains, frozen on dry ice and stored at -85 °C until assayed. The kinetic properties of α -adrenergic, β -adrenergic and serotonergic receptor binding sites were measured in the cortex and those of dopaminergic binding sites were measured in the striatum. The cortices were suspended in 19 volumes of ice-cold 50 mM Tris-HCl buffer (pH 7.7 at 23 °C) containing 0.1% ascorbic acid. The striata were suspended in 39 volumes of ice-cold buffer containing 50 mM Tris-HCl, 2 mM CaCl₂, 5 mM KCl, 120 mM NaCl, 1 mM MgCl₂, 0.1% ascorbic acid and 10 μ M pargyline (pH 7.7 at 25 °C). The tissues were disrupted using a Brinkmann polytron (setting 6, 30 s), and the homogenates centrifuged at 48,000g for 10 min. The pellets were rehomogenised and centrifuged as before. The cortical pellets were resuspended in 19 volumes of buffer and the striatal pellets in 39 volumes of buffer (based on original weight).

Aliquots of tissue equivalent to 10 mg of cortex and to 5 mg of striatum were assayed.

Binding of ^3H -*l*-dihydroalprenolol (^3H -DHA) to β -adrenergic receptors was carried out at 23 °C for 15 min in 0.5 ml 50 mM Tris-HCl buffer (pH 8.1 at 23 °C) containing 0.1% ascorbic acid^{11,12}. Assays were carried out in sextuplicate with half the tubes containing 20 μM propranolol to assess nonspecific binding. The α -adrenergic receptor binding sites were assayed using ^3H -dihydroergocryptine (^3H -DHE) and ^3H -WB-4101 as the binding ligands¹³⁻¹⁶. Dihydroergocryptine is a mixed agonist-antagonist at α -adrenergic receptors and is thought to bind to both an agonist and an antagonist α -adrenergic receptor site in our assay conditions^{13,14}. The antagonist WB-4101 seems to bind only to the α -adrenergic antagonist site¹⁶. Incubations were carried out in sextuplicate at 25 °C for 45 min with ^3H -DHE and for 15 min with ^3H -WB-4101 in 2 ml 50 mM Tris-HCl buffer (pH 7.7 at 25 °C) containing 0.1% ascorbic acid. Nonspecific binding was determined by adding 100 μM *l*-NA to half the tubes. The serotonergic binding site was assayed using ^3H -serotonin (^3H -5-HT) as the binding ligand¹⁷. Tissues were preincubated for 10 min at 37 °C in 2 ml 50 mM Tris-HCl buffer (pH 7.1 at 37 °C) containing 0.1% ascorbic acid, 4 mM CaCl_2 and 10 μM pargyline, an inhibitor of monoamine oxidase. After preincubation, the tubes were returned to ice and ^3H -5-HT was added in sextuplicate. Half the tubes also contained 20 μM nonradioactive 5-HT to assess nonspecific binding. Incubations were carried out for 10 min at 37 °C. The dopaminergic binding site in the striatum was assayed in quadruplicate, using ^3H -spiroperidol (^3H -spiro) as the binding ligand^{18,19}. Tissues were preincubated for 5 min at 37 °C and returned to ice. To assess nonspecific binding, 10 μM (+)butaclamol was added to half the tubes. Incubations were carried out for 20 min at 37 °C in 0.5 ml of the same buffer used to homogenise the tissue. All incubations were terminated by adding 4 ml of ice-cold buffer to each tube and rapidly filtering the samples under reduced pressure through Whatman GF/B glass fibre filters. The tubes and filters were then rapidly rinsed four times with 4-ml aliquots of cold buffer. Filters were transferred to counting vials containing scintillation fluid and counted in a Searle mark III scintillation counter at an efficiency of

Fig. 1 Scatchard plot of specific ^3H -*l*-dihydroalprenolol binding to cortical fractions from control (●) and ECS-treated (▲) rats. The concentrations of ^3H -DHA used varied from 0.5 to 5.0 nM. This experiment is representative of results obtained from three separate experiments. Data points are the means from 2 control and 2 ECS-treated rats, each assayed in triplicate. Slopes and intercepts of the lines were determined by the method of least squares.

Table 1 Maximum specific binding and dissociation constants of monoamine receptor ligands in brain fractions from control and ECS-treated rats

Region	Treatment	Maximum binding (pmol per g tissue)	Dissociation constant (nM)
Cortex	^3H -DHA Control	10.9 ± 0.9	2.7 ± 0.5
	^3H -DHA ECS	7.8 ± 0.6*	2.1 ± 0.2
	^3H -DHE Control	28.1 ± 1.6	1.9 ± 0.3
	^3H -DHE ECS	27.0 ± 0.7	1.9 ± 0.1
	^3H -WB-4101 Control	7.8 ± 0.5	0.28 ± 0.01
	^3H -WB-4101 ECS	7.9 ± 0.4	0.24 ± 0.02
Corpus striatum	^3H -5-HT Control	15.8 ± 2.0	8.5 ± 1.4
	^3H -5-HT ECS	14.7 ± 1.4	7.1 ± 1.1
	^3H -Spro Control	24.0 ± 0.7	0.33 ± 0.07
	^3H -Spro ECS	23.3 ± 0.7	0.37 ± 0.08

Maximum specific binding and dissociation constants were determined from least-squares fit to Scatchard plots of the data. The results are the mean ± s.e.m. from 5–8 rats. Statistical analyses were carried out by grouped Student's *t*-test.

* $P < 0.02$.

40–42%. In these conditions, specific binding, defined as the difference between counts bound to tissue in the presence and absence of saturating concentrations of nonradioactive ligand, was between 60 and 90% depending on the assay and the concentration of the ^3H -ligand.

There was no apparent alteration in the α -adrenergic, β -adrenergic or serotonergic receptor binding characteristics after a single ECS. However, Scatchard analysis²⁰ of ^3H -DHA binding to cortical membranes indicated that 7 days of ECS reduced the number of binding sites by approximately 25% compared with the handled controls (Fig. 1). There was no change in the apparent affinity of the binding sites for ^3H -DHA. In contrast to the changes observed in β -adrenergic binding, 7 days of ECS produced no apparent alterations of α -adrenergic or serotonergic binding in the cortex nor of dopaminergic binding in the corpus striatum (Table 1).

As the animals were not anaesthetised, it is possible that a nonspecific stress response contributed to the reduction in the β -adrenergic receptor seen following chronic ECS. To ascertain whether another form of stressful situation would decrease ^3H -DHA binding, we investigated the effects of electric foot shock on β -adrenergic binding. Foot shock was applied by placing the rat in a 28 × 20 × 15 cm test chamber containing a grid floor connected to a constant current shock source with a shock scrambler (BRS Foringer shock generator scrambler model SGS-001). The rats received foot shocks of 2 mA intensity and 1.0 s duration at a variable time (VT) schedule with a mean interval of 15 s. The rats were shocked daily for 10 min for 7 consecutive days. Control rats were treated similarly except that no current was delivered to the chamber grid. Rats were decapitated 24 h after their last session in the test chamber. Cortical β -adrenergic receptor binding of 0.7 nM ^3H -DHA in tissue from control ($n = 6$) and foot shock-treated ($n = 6$) rats was found to be 1.76 ± 0.18 and 1.64 ± 0.19 pmol per g tissue, respectively, and 7.28 ± 0.26 and 7.13 ± 0.23 pmol per g using 4.5 nM ^3H -DHA. This absence of reduction in specific ^3H -DHA binding with foot shock suggests that nonspecific stress alone was not a major factor in reducing the density of β -adrenergic receptors in the brains of rats subjected to chronic ECS.

Electroconvulsive shock has been shown to affect several biochemical parameters of the central noradrenergic system. It increases the activity of tyrosine hydroxylase,²¹ endogenous NA concentration²² and turnover^{22,23}, and the release of NA²², and decreases the high affinity uptake of NA into synaptosomes²⁴. Through these effects, ECS might be expected to increase the availability of NA at the synapse²² and could initiate a neurochemical adaptation at the receptor level. Sulser *et al.* have

reported that administration of ECS to rats for 8 days reduces the activity of the NA-stimulated cyclic AMP-generating system in limbic forebrain^{2,3}.

The development of neurotransmitter receptor subsensitivity following exposure to agonist compounds or drugs that potentiate the action of existing transmitters has been reported previously^{6-10,26-30}. We report here another example of the development of receptor subsensitivity, the decreased density of β -adrenergic receptors in rat brain cortex following chronic ECS. It is particularly interesting that chronic ECS results in a decrease in cortical β -adrenergic receptor density similar in magnitude and selectivity to that following chronic administration of desipramine⁷. In both cases the time course of reduction of β -adrenergic receptor density closely parallels the reported decrease in activity of the NA-stimulated cyclic AMP-generating system^{2,3}.

These results indicate that the effects on neurotransmission at the β -adrenergic synapse produced by chronic administration of tricyclic antidepressant drugs or ECS are opposite to the effects produced by acute administration of these treatments. Thus, although both tricyclic antidepressants and ECS increase the amount of NA available to interact with receptors in the synapse, the reduction in the number of β -adrenergic receptors after chronic treatment would be expected to result in a decrease in the transmitted message. The reduction in activity of the NA-stimulated cyclic AMP-generating system following chronic administration of either tricyclic antidepressants or ECS¹⁻⁴ seems to support this.

The selectivity of the response of neurotransmitter receptors to chronic ECS reported here agrees closely with that reported for desipramine⁷ and suggests that an adaptation of central β -adrenergic receptors may be important for the therapeutic effects of antidepressant treatment.

We thank Susan Treiser, Paul Iadarola and Dr Joe Moerschbacher for assistance. This study was supported by USPH 12566 and NASA NCA20R258701.

Bio-selective membrane electrode using tissue slices

MEMBRANE electrodes based on living bacterial cells¹ as biocatalysts have been shown to be useful sensors for amino acids and other biomolecules. We report here that we have now developed a highly effective membrane electrode for glutamine using slices of porcine kidney tissue as the biocatalytic layer. This tissue-based electrode yields excellent selectivity and sensitivity while having the additional advantages of simplicity and low cost. Further, the tissue-based electrode shows a much longer useful lifetime than comparable electrodes prepared with the isolated porcine enzyme.

The electrode assembly (Fig. 1) was prepared by immobilising a thin (~0.05 mm) slice of porcine kidney at the surface of an ammonia gas sensing membrane electrode (Orion model 95-10) by means of a dialysis membrane or a mesh of monofilament nylon. Pork kidneys were obtained from freshly killed animals and stored at 4 °C until use. In separate experiments the kidney slices showed high glutaminase activity as indicated by their ability to metabolise glutamine rapidly to products including ammonia. Moreover, the enzyme activity was retained within the intact tissue over extended time periods. This finding is consistent with the view that the glutaminase enzyme is situated in the kidney cell mitochondria².

Evaluations of the potentiometric response of the kidney slice electrode were made at 26 °C in 0.1 M phosphate buffer, pH 7.8, containing 0.02% sodium azide as preservative. Between experiments, the electrodes were stored in the buffer at room temperature. Figure 2 shows a typical calibration curve of the electrode for L-glutamine. The slope, linear range and detection

Fig. 2. Potentiometric response and selectivity of the kidney-based electrode in 0.1 M phosphate buffer, pH 7.8, with 0.02% sodium azide preservative at 26 °C. Solid line shows the electrode response as a function of glutamine concentration over the range 2×10^{-2} to 5×10^{-5} M. Dotted region shows the maximum response to the 13 possible interference compounds tested.

limit remained unchanged over at least 28 d of electrode use. Typically, the electrode attained a steady potential value within 5–7 min of each addition of glutamine to the test solution.

The kidney tissue electrode yielded negligible response to compounds causing possible interference such as urea, L-alanine, L-arginine, L-histidine, L-valine, L-serine, L-glutamic acid, L-asparagine, L-aspartic acid, D-alanine, D-aspartic acid, glycine or creatinine. This high degree of potentiometric selectivity compares favourably with that of conventional electrodes³.

Parallel electrode experiments were also carried out using the isolated porcine kidney glutaminase enzyme (Sigma, grade Vi), known to be thermally unstable⁴. Small volumes (~15 μ l) of enzyme suspension were immobilised at the surface of the ammonia gas sensing electrode by means of a dialysis membrane, and electrode response to L-glutamine was evaluated in the buffer medium. Freshly prepared enzyme electrodes yielded moderate potentiometric response (44 mV per 10-fold change in substrate concentration) but lost more than 50% of their activity within 2 d and showed negligible response after 4 d at room temperature. Thus, it is clear that the kidney tissue electrode is a very substantial improvement, in terms of lifetime and response, over the conventional enzyme electrode. In view of continuing advances³ in the development of potentiometric membrane electrodes, other tissue-based electrodes of fundamental and practical significance can be expected.

Elevation of protein synthesis is a complex response to fertilisation

PROTEIN SYNTHESIS in unfertilised eggs of the sea urchin proceeds at a low rate. However, fertilisation triggers a series of reactions beginning with changes in intracellular cation concentrations within a few seconds of sperm entry and extending to a cascade of more complex events¹. As these events are sequential in time, each might depend on the preceding event, or there might be a parallel series of independent pathways. The latter hypothesis was shown to be correct by Epel *et al.*², who demonstrated that artificial activation with ammonia failed to initiate events such as sodium influx and the cortical reactions but did initiate a variety of others including potassium conductance, protein synthesis, DNA synthesis and mRNA polyadenylation.

Fig. 1. Elevation of protein synthesis as a function of activation method. Eggs (2×10^5 per ml, total volume 35 ml) were pulsed with $10 \mu\text{Ci ml}^{-1}$ ^{35}S -methionine ($1,130 \text{ Ci mmol}^{-1}$) for 60 min at 17 °C. The sea water contained 50 mg ml^{-1} each of penicillin and streptomycin adjusted to pH 8.1 with NaOH. After incubation, the eggs were washed 3 times by pelleting them at 200 g. The final pellet was resuspended in 15 ml and distributed equally to each of 3 culture vessels at 6.7×10^4 eggs ml^{-1} , final volume 35 ml). At time zero, 2.0 ml of sea water was added to one of the vessels (■), 2.0 ml 200 mM NH_4Cl was added to the second culture (▲) and 2.0 ml of concentrated sperm suspension (1 drop sperm as obtained from the gonads in 5 ml sea water) was quickly squirted into the third culture (●). Taking precautions to avoid cross-contamination, 1.0-ml samples were removed from each culture at 5 min intervals. The samples were squirted directly into an equal volume of ice-cold 20% trichloroacetic acid (TCA) plus 50 mM methionine. The eggs and embryos were pelleted, washed once with the TCA mixture, and heated to 90 °C for 30 min. During heating each tube was vigorously agitated several times. Precipitates were collected on Whatman glass fibre filters (GF/C), washed 4 times with 2 ml 10% TCA plus 25 mM methionine, and once with 95% ethanol, and the disks were then placed in scintillation vials. Protein was digested off the disks in sealed vials by adding 0.5 ml 0.2 M NaOH and heating to 60 °C for 2 h. The hydrolysates were cooled, neutralised with 1 M acetic acid, dissolved in 10 ml Instagel scintillation fluid, and counted.

We have been studying the elevation of protein synthesis in detail. The rate of protein synthesis increases severalfold during the early cleavage stages³ and eventually reaches an absolute rate which is 100 times higher than that in the mature oocyte⁴. Kaumeyer *et al.*⁵ and Jenkins *et al.*⁶ have demonstrated that unfertilised eggs contain 'masked' messenger ribonucleoprotein particles which are not translatable *in vitro* unless modified or deproteinised. Most of the increase in the rate of protein synthesis following fertilisation is due to the recruitment of this oogenic mRNA as a result of unmasking⁷. However, a significant portion of the rise also results from an increase in translational efficiency⁸. As defined by Palmiter⁹, translational efficiency is the number of completed polypeptides released per unit time per message. The change in efficiency following fertilisation of sea urchin eggs is reflected in an increase in the rate of ribosome movement (that is, the time required to complete an average size protein decreases after fertilisation) coupled to a concomitant increase in initiation rate. The net effect on protein synthesis of an increase in number of mRNAs available for translation and an increase in translational efficiency is multiplicative. We present evidence here that these two processes are under separate controls.

As Fig. 1 shows, in *Strongylocentrotus purpuratus* eggs the rise in protein synthesis induced by ammonia lags behind the rise caused by fertilisation. The same response was observed in a different species by Epel *et al.*². They found that even though the

Fig. 2 Determination of ribosome transit time for ammonia-activated, unfertilised eggs. A culture of eggs (32,000 per ml) in sea water containing penicillin and streptomycin (pH adjusted to 8.1 with NaOH) was treated with sufficient 200 mM NH_4Cl to bring the final concentration of NH_4^+ to 10 mM. Five minutes later, ^{35}S -methionine was added ($5 \mu\text{Ci ml}^{-1}$; 900 Ci mmol^{-1}) plus unlabelled methionine to yield a final exogenous amino acid concentration equal to $0.32 \mu\text{g ml}^{-1}$. The addition of isotope was defined as time zero, after which 5.0-ml samples were removed and processed as described elsewhere⁸. Transit times were obtained by multiplying by two the distance between the extrapolated 'total' and 'soluble' lines. All extrapolations were based on those points after the polysome phase had reached steady-state labelling, when the flow of radioactivity into total and soluble proteins is linear⁸. Points used for extrapolation are outlined. ●, Total incorporation; ■, incorporation into soluble proteins; ▲, incorporation into polysomes.

Table 1 Ribosome transit times for ammonia-activated eggs

Experiment	Isotope	Transit time (min)
UF eggs	^3H -Leu	41.6
UF eggs	^{35}S -Met	38.6
		Average = $40.4 \pm 4.0^\dagger$
30 min zygotes	^3H -Leu	14.0
30 min zygotes	^{35}S -Met	19.0
		Average = $18.0 \pm 4.4^\dagger$
NH_3 -activated eggs	^3H -Leu*	33.2
NH_3 -activated eggs	^{35}S -Met*	39.1
		Average = $36.2^\ddagger$

Cultures of unfertilised (UF) eggs and zygotes were handled as described elsewhere⁸. In activation experiments, unfertilised eggs in Millipore-filtered sea water containing $50 \mu\text{g ml}^{-1}$ each of penicillin and streptomycin (pH adjusted to 8.1) were treated with sufficient 200 mM NH_4Cl to bring the final concentration of ammonium ion to 10 mM. Five minutes later, either ^3H -leucine (New England Nuclear, $57.4 \text{ Ci mmol}^{-1}$) or ^{35}S -methionine (Amersham, 900 Ci mmol^{-1}) was added to the culture. The addition of isotope was defined as time zero after which samples were removed and processed as described in Fig. 2.

* The total final exogenous amino acid concentrations, including isotope, in $\mu\text{g ml}^{-1}$ were 0.32 for methionine (32,000 eggs ml^{-1}) and 1.45 for leucine (23,000 eggs ml^{-1}). The final exogenous radioactivity was $5 \mu\text{Ci ml}^{-1}$ in each experiment.

† The averages of 5 determinations for each stage of development ± 1 s.d. The 2.2-fold difference in means yields a $t = 7.48$ for 8 degrees of freedom or $p < 0.001$, indicating that the difference is significant at the 99% confidence level in a standard t test⁸.

‡ The average transit time for ammonia-activated eggs is within 1 s.d. of the unfertilised egg. A χ^2 test¹² for group variance indicates that this value is probably a subset of the parent group unfertilised egg value, but not of the parent group zygote value.

rise in protein synthesis induced by ammonia lagged behind the rise caused by fertilisation, the same level of recruitment of ribosomes (and thus of mRNA) into polysomes was attained in both ammonia-activated and fertilised eggs. These observations suggested to us that ammonia activation may cause unmasking of mRNA but not stimulate a change in translational efficiency.

To test the hypothesis that ammonia-activated eggs recruit mRNA but fail to increase the rate of ribosome movement, we measured the average transit time in ammonia-activated eggs using the method developed for time-course incorporation into sea urchin eggs and embryos as shown in Fig. 2. The results are summarised in Table 1. We found that ammonia-activated eggs require as much time as unfertilised eggs to complete an average size polypeptide. This is about twice as long as the time required by zygotes. Thus, the increase in protein synthesis caused by ammonia treatment is the result only of an increase in the amount of available mRNA in the absence of an increase in the rate of ribosome movement. Therefore, the two events responsible for the rise in protein synthesis following fertilisation of the *S. purpuratus* egg must be independent of one another.

The normal acceleration of synthetic events following fertilisation seem to result from a transient elevation in intracellular pH caused by a massive influx of sodium ions coupled to a loss of protons¹⁰. Ammonia is believed to function as an activating agent by raising the internal pH of the egg. Weak organic bases enter the unfertilised egg in the uncharged form and then gain protons, thus raising the intracellular pH and mimicking the normal Na^+/H^+ exchange¹¹. This rise in internal pH must stimulate unmasking, but as ammonia does not stimulate a change in the rate of ribosome movement, the increase in translational efficiency in zygotes must depend on an as yet unidentified mechanism.

Efficiency of protein synthesis after fertilisation of sea urchin eggs

ELUCIDATION of the mechanisms involved in the cytoplasmic control of protein synthesis is essential for an understanding of the initiation of embryogenesis. On fertilisation, echinoid eggs increase their rate of protein synthesis many-fold, independent of any increase in ribosomal or mRNA synthesis¹⁻⁴. Within 2 h of fertilisation the number of ribosomes in polyribosomes increases, about 25-fold without any change in the size distribution of poly ribosomes^{5,6}. In addition, the polyribosome number doubles again by gastrulation. However, the total rate of protein synthesis increases 113-fold from egg to gastrulation⁷. The discrepancy between the number of ribosomes recruited into polyribosomes, an increase of ~50 fold, and the total increase in the rate of protein synthesis, a 113-fold increase, could be explained if there were also an increase in the rate of movement of ribosomes along each message (elongation) and/or an increase in the rate of release of completed peptides (termination). We report here that the translational rate is increased about 2.5-fold after fertilisation in the sea urchin, *Strongylocentrotus purpuratus*. The average transit time (elongation plus termination time for an average-sized peptide) was measured for these eggs and several stages of embryos.

The transit times of eggs and embryos of *S. purpuratus* were measured at 12 °C by modifications of Fan and Penman's time course method^{8,9}. The low temperature used is that of the sea urchin's normal habitat and gives accurately measurable, slow elongation rates. The time course method is independent of variations in the rate of initiation of peptide synthesis, the number of polyribosomes and the specific activity of the amino acid pools. The method compares the ³H-amino acid incorporation into total peptides (incomplete nascent peptides still covalently bound to tRNA on the polyribosomes plus completed, released peptides) and the incorporation into released peptides determined after removal of the polyribosomes by centrifugation. One transit time after the amino acid pools have equilibrated, the rates of incorporation into total peptides and released peptides should be equal and graphically form two parallel lines separated by one-half the transit time⁸. In our experiments these lines, shown in Fig. 1 as open circles and solid circles respectively, did not become parallel but diverged with time. Presumably, this occurs because newly synthesised histones and other basic proteins attach to large deoxyribonucleoprotein or ribonucleoprotein particles¹³⁻¹⁵ and are removed during centrifugation. Analysis of the polyribosomal pellets for peptidyl-tRNA and peptides by DEAE-cellulose chromatography^{9,12} did show the presence of 15-55% released peptides. When the counts in the released peptide fraction

Fig. 1 Representative determinations of the average mRNA transit time in *S. purpuratus* unfertilised eggs (a) and 2-4-cell embryos (b). The time course methods of Fan and Penman⁸ and Palmiter⁹ were modified for sea urchins to determine elongation rates. Eggs and embryos were cultured in rotating tubes at 12 °C with ³H-leucine at various specific activities and at various culture densities as specified in Table 1. Samples of 1 ml were removed at the times indicated and added to 40 ml of -2 °C buffer I (0.2 M KCl, 0.05 M triethanolamine, 0.01 M MgOAc₂, pH 7.8) to stop synthesis and preserve polyribosome structures. The eggs and embryos were collected by centrifugation at 500g_{max} and washed by an additional 40 ml of buffer I; 1 ml of buffer I containing 2-3 mg ml⁻¹ purified yeast 4S RNA to compete for ribonuclease activity, 0.5% Triton X-100 and 0.5% Na deoxycholate was added to each sample. The eggs or embryos were homogenised either by rapid passage through a no. 20 G needle fitted with 22-μm Nitex Bolting or with a dounce homogeniser. The fertilisation membrane of the embryos had been softened by exposure to 50 mM 3-amino-1,2,4-triazole during fertilisation¹⁰. The homogenates were centrifuged in conditions normally used for removal of mitochondria or larger organelles, that is, at 14,000g_{max} for 10 min at 2 °C. The incorporation of ³H-leucine into precipitable peptides was essentially identical in aliquots taken before and after this centrifugation (±7%), indicating complete homogenisation of the eggs and embryos and total solubilisation of membranes, organelles and labelled cellular proteins. Aliquots from the low-speed supernatant, therefore, represented total incorporation (○). To eliminate sampling variations of about 10% the incorporation data were normalised to an average protein concentration after the determination of the total protein content by a modified Lowry procedure¹¹. The low-speed supernatant was centrifuged at 138,000g_{max} for 2 h at 2 °C in a Beckman type 65 rotor to remove polyribosomes. Aliquots of the resulting high-speed supernatant were removed to measure completed proteins released from the polyribosomes (●). All aliquots for counting were precipitated in 7.5% (w/v) trichloroacetic acid containing 0.1 mg ml⁻¹ unlabelled L-leucine, and collected on glass fibre disks, digested with N-chlorosuccinimide (Amersham) and counted in a toluene-based scintillant. They were not heated because it is not necessary to hydrolyse the ³H-leucyl-tRNA which occurs in both the aliquots of total incorporation and the released peptides fraction, and because heating selectively removes small peptidyl-tRNAs from the total incorporation. Peptides and peptidyl-tRNA in the S-138 pellet were separated on DEAE-cellulose^{9,12} as described in Fig. 2. Counts from the proportion of the pellet that eluted as peptides were added to those from the high-speed supernatant for total released peptides (Δ). The horizontal distance between the parallel lines for total incorporation (○) and total released peptides (Δ) represent one-half an average transit time, which was 37 and 14.5 min, respectively, for a and b.

recovered from the polyribosomal pellets were added to those of the released peptides in the high-speed supernatant, parallel lines were obtained and transit times determined (Fig. 1, open circles and triangles). The 2-h centrifugation time for polyribosomes was chosen for removal of peptidyl-tRNA with minimal co-centrifugation of released peptides (Fig. 2).

Table 1 summarises the results obtained by time course measurements such as those in Fig. 1. No variation in stage-specific transit times was observed by varying culture conditions such as the concentrations of amino acids or centrifugation times. This showed that, as predicted, the transit times we measured were independent of the specific activities of the amino acid pools, and that our analysis of the released peptides co-sedimenting with polyribosomes was valid and accurate. At 12 °C the transit time is about 69 min per average length peptide chain in unfertilised eggs, which is about 2.5-fold longer than for embryos (Table 1). The transit times were 20-24 min for pre-cleavage embryos, 29 min for embryos undergoing 2nd cleavage during the experiment, and 28-32 min for embryos in the 4th cleavage. Therefore, the translational rate increased as early

Table 1 Average mRNA transit time in *S. purpuratus*

Stage	Transit time (min at 12 °C)	μM leucine†	mCi ^3H per μmol leucine	Culture density‡
Unfertilised eggs	66	0.52	24.1	13,800
	64–69*	0.93	13.4	32,100
	72–78	1.36	12.3	21,400
	66–70	2.42	8.3	57,100
Average	69			
Fertilised eggs (60 min, 12 °C)	20–24	199.0	0.10	30,900
Embryos (2–4 cells)	29*	49.8	0.25	13,100
Embryos (16–32 cells)	29	82.9	0.20	28,600
Embryos (16–32 cells)	28–32	199.0	0.10	28,600

The transit times were determined as in Fig. 1 except that samples marked with an asterisk were centrifuged for 2.5 h. The range of graphical error is given where it is greater than 1 min.

† The initial concentration in seawater. Because the rate of amino acid uptake by eggs is very slow compared with embryos¹⁶, the concentration and radioisotopic activities of amino acids is necessarily very different.

‡ The number of eggs or embryos per ml was calculated assuming 40 ng protein per egg or embryo¹⁷.

after fertilisation as we were able to obtain accurate transit times, and did not vary significantly through these early stages.

How valid is the measurement of the transit times, which depend on the weight average molecular weight (MW) of the peptides being synthesised? Bradhorst¹⁸ identified 400 distinctly resolved peptides synthesised before and 30–60 min after fertilisation of *Lytechinus pictus* eggs and found that at least 90% of the spots co-electrophoresed and had similar relative intensities. He found similar results for *S. purpuratus* eggs and zygotes and concluded that there was a quantitative rather than a qualitative regulation of the translation of stored mRNA after fertilisation. Other evidence which supports this conclusion is the similar sedimentation of newly synthesised peptides from eggs and embryos of *L. pictus* in SDS-urea sucrose gradients¹⁹, a similar average MW distribution of *S. purpuratus* nascent chains on SDS-polyacrylamide gels²⁰, and a similar size distribution of *S. purpuratus* polyribosomes²⁰. Therefore, the increased translational rate we observed after fertilisation is not due to a decrease in the weight average peptide length.

At first glance, our measured transit times of about 29 min at 12 °C for embryos seem long compared with those of mammalian systems measured at 36 °C and summarised in Table 2. However, Craig^{21,22}, in a very thorough and careful manner, has shown that the transit times increase dramatically (7–50-fold) at low temperatures (Table 2). Mouse L-cells synthesising an average peptide chain length of 85,000 daltons have an average transit time of 22 and 13 min at 10 °C and 15 °C, respectively. Reticulocytes synthesising α and β -globin (MW = 17,000) have an average transit time of 20.7 and 6.4 min at 10 °C and 15 °C, respectively. Therefore, the transit times observed for *S. purpuratus* embryos are not unusually long compared with other systems at low temperatures, especially considering tissue variations such as those in Table 2 for hamster ovary cells and chick oviduct at 35–36 °C. However, the transit time of 69 min for unfertilised *S. purpuratus* eggs is unusually long, presumably reflecting the quiescent state of the eggs and their need to conserve materials for later development.

In a paper published after submission of our manuscript, Brandis and Raff²⁰ similarly report long transit times in *S. purpuratus* eggs at 16.5 °C and show a 2–3-fold acceleration following fertilisation. Our observations at 12 °C are in close quantitative agreement if the Q_{10} for elongation is 3 in sea urchins. Changes in elongation rates have also been observed, by Palmiter⁹, in chick oviducts. Stimulation of the oviduct with oestrogen caused a 1.5-fold increase in the elongation rate compared with unstimulated oviduct.

There are several possible reasons for the failure of others to detect the difference between the translational efficiency of eggs and of embryos in sea urchins. For example, Humphreys¹⁹ measured the incorporation of ^{14}C -amino acids into peptides

after only 10 and 20 min of labelling at 18 °C. This was probably too short to achieve equilibrated labelling of the nascent peptides on the polyribosomes, especially for eggs in which he observed an 8-min lag before labelling of the total cellular peptides became linear. Both linear kinetics and complete labelling of nascent peptides are necessary for accurate determinations of transit times. Furthermore, Craig has recently demonstrated the temperature dependence of transit times in mammalian systems^{21,22}; this makes the 1–2-min transit times determined by Humphreys¹⁹ for eggs and embryos at 18 °C seem unreasonably rapid.

Felicetti *et al.*²³ found that, within minutes of fertilisation of *Paracentrotus lividus* eggs, there was a threefold increase in the activity of T1 elongation factor plus a 1.5-fold increase in the activity of T2 elongation factor. The rapid activation of these factors suggests mobilisation of pre-existing proteins. Whether the activity of elongation factors increases only to keep pace with increasing numbers of polyribosomes or whether they are also responsible for increased rates of translation has not been known, but it is now apparent that some of the factors contribute to an increase in translational efficiency.

As the polyribosome size in embryos is the same as that in eggs²⁰, initiation factors must also be available to keep pace with both the increased translational efficiency and the increased recruitment of ribosomes into polyribosomes. Whether these initiation factors pre-exist in an active form, are mobilised to an active form at fertilisation, or are newly synthesised, is not known. However, in the mid-blastula stage the supply of initiation factors does not keep pace with the demand, as about 50% of the mRNAs are not fully loaded with ribosomes²⁴.

What is the relationship of our results to previous studies on the activation of protein synthesis at fertilisation? We propose that the increased rate of elongation after fertilisation will account for observed differences between the increased numbers of ribosomes in polyribosomes^{5,6} and the changes in the absolute rate of protein synthesis⁷. The observed recruitment of ribosomes and mRNA into polyribosomes after fertilisation could occur by a release of mRNAs from inhibited, preformed messenger ribonucleoprotein particles^{4,14} and/or by an increase in the rate with which ribosomes attach to mRNA and initiate protein synthesis^{25–28}. Humphreys⁵ accurately determined the per cent of ribosomes in polyribosomes in *L. pictus* by measuring the ribosomal RNA content of these fractions. He found an average of 0.75% of the ribosomes in polyribosomes in unfertilised eggs and about 20% as polyribosomes in 2–6-h (18 °C)

Fig. 2 Determination of optimum centrifugation times for the polyribosome fraction. The low-speed supernatant from eggs labelled with ^3H -leucine was centrifuged at 138,000 $\times g_{\text{max}}$ at 2 °C for 1, 2 and 3 h to pellet polyribosomes. The ribonucleoprotein pellets thus obtained were subjected to DEAE-cellulose chromatography to separate released peptides and peptidyl-tRNA^{9,12}. The polyribosomal pellets were dissolved overnight at 0 °C in 0.5 ml of 3 M LiCl, 6 M ultra pure urea (Schwarz/Mann), 50 mM NaOAc and 5 mM dithiothreitol, pH 5.2, and stored at –80 °C. The solubilised pellet was diluted 30-fold with 8 M ultra pure urea at pH 5.4 containing 6 mM β -mercaptoethanol and applied at room temperature to a 0.5 $\times$ 1 cm DEAE-cellulose column pre-equilibrated with buffer II (0.1 M NaOAc, 8 M ultra pure urea, 6 mM β -mercaptoethanol, pH 5.6). Peptides were eluted with buffer II and peptidyl-tRNA was eluted with buffer III (0.75 M NaOAc, 8 M ultra pure urea, 6 mM β -mercaptoethanol, pH 5.6), and buffer IV (1 M KCl, 0.1 M Tris-HCl, 8 M ultra pure urea, 6 mM β -mercaptoethanol, pH 7.4). The total incorporation associated with the polyribosomal pellet (O) and the fraction occurring as ^3H -peptidyl-tRNA (●) are shown. At 2 h peptidyl-tRNA in the pellet reaches a maximum.

Table 2 Temperature dependence of transit times

Tissues	Transit time (min)			MW*	Ref.
	10 °C	15 °C	35–36 °C		
Mouse L-cells	22.0	13.0	2.0	85,000	21
Reticulocyte cells	20.7	6.4	0.42	17,000	22
Hamster ovary cells			2.0	85,000	8
Chick oviduct			3–4	38,000	9

* Weight average MW.

embryos, a total increase of 27-fold. By measuring the absorption of polyribosomes and monoribosomes at 260 nm, Infante and Nemer⁶ found the percentage of ribosomes as polyribosomes to be 5% in unfertilised eggs, 25% in early cleavage stages, 50% in blastulae and 40% in gastrulae of *S. purpuratus*, a stimulation of 8–10-fold. The largest discrepancy between these data and those for *L. pictus* is for the unfertilised egg. How much of this difference is due to species variation and how much to methods is not known. If, however, we assume that Humphrey's more accurate method establishes the lower limit for polyribosomes in unfertilised eggs at slightly less than 1%, the maximum increase in polyribosomes in *S. purpuratus* by gastrula stage would be 50-fold. In the absence of better data we will use this value for comparison with changes in the total rates of protein synthesis.

Absolute rates of protein synthesis are difficult to obtain because of the 25-fold slower uptake of amino acids by eggs compared with embryos¹⁶ which results in a large difference in the specific activities of their amino acid pools. Regier and Kafatos⁷, however, measured the specific radioactivity of precursor aminoacyl-tRNA pools to obtain accurate data. They found a 113-fold stimulation in the absolute rate of protein synthesis in *S. purpuratus* at the gastrula stage compared with unfertilised eggs. Although this value must theoretically include the 50-fold increase in ribosomes as polyribosomes by the gastrula stage, it is more than twice the latter. As newly synthesised ribosomes are less than 10% of the total ribosome population by gastrulation and as there is also some degradation of old ribosomes²⁹, increased numbers of ribosomes cannot account for any significant increase in rates of protein synthesis. The difference between the 113-fold stimulation in the absolute rate of protein synthesis and the 50-fold increase in polyribosomes can be accounted for by the increased efficiency of translation we report here³⁰.

The unmasking of maternal messenger RNA and/or the increased availability of ribosomal subunits to initiate protein synthesis result in a very large stimulation of protein synthesis after fertilisation, as shown by Humphreys³. However, the additional 2.5-fold increase in the rates of elongation can no longer be ignored as contributing to the observed activation of these eggs and the probable doubling of the growth rate of these embryos.

We thank Deborah C. Hall for technical assistance and Marcia A. Bechtold, Michael V. Danilchik and Randall T. Moon for helpful suggestions. 2-5A synthetase: assay, distribution and variation with growth or hormone status

PROTEIN SYNTHESIS in cell-free systems from interferon-treated cells and rabbit reticulocyte lysates is exceptionally sensitive to inhibition by double-stranded RNA (dsRNA)^{1,2}. Two distinct mechanisms seem to be involved: (1) inactivation of initiation factor eIF2 by dsRNA-mediated phosphorylation and (2) degradation of mRNA by one or more nucleases which are activated by sub-nanomolar levels of an unusual oligonucleotide, pppA2'p5'A2'p5'A (refs 3–10). The enzyme responsible for synthesising pppA2'p5'A2'p5'A requires dsRNA for activity, binds to poly(I) · poly(C)-Sepharose, and can be used conveniently in this insoluble form to synthesise pppA2'p5'A2'p5'A and related oligomers^{4,11}, collectively referred to as 2-5A. The discovery of relatively high levels of 2-5A synthetase in rabbit reticulocyte lysates¹² raised the possibility that the 2-5A system might be found in other cells which have not been treated with interferon and might, therefore, have a wider significance. We have developed a more convenient assay for the synthetase based on its activity when bound to poly(I) · poly(C)-paper rather than poly(I) · poly(C)-Sepharose and show here that this enzyme is distributed widely in mammalian cells. Moreover, different cells or tissues have widely differing levels of this enzyme and in the case of chick oviducts there is a substantial increase in synthetase level after withdrawal from stimulation by oestrogen.

The 2-5A synthetase from interferon-treated mouse L cells or rabbit reticulocyte lysates was equally stable and active when bound to poly(I) · poly(C)-paper or poly(I) · poly(C)-Sepharose. However, the paper has a number of advantages, especially reproducibility of preparation, stability to storage and convenience in use, particularly with multiple small volumes. There is little or no loss of poly(I) · poly(C) from the paper during prolonged incubation (>10 d) with the bound enzyme, allowing the same paper to be re-used several times. The paper-bound enzyme retains full activity on storage for at least 6 weeks at –70 °C.

One square centimetre of poly(I) · poly(C)-paper was at least five times more than enough to bind all the 2-5A synthetase available in a 200-μl extract from reticulocytes or interferon-treated L cells. There was a linear relationship between the amount of extract used in the assay and the amount of 2-5A synthesised. When different amounts of cell sap from interferon-treated cells were mixed with sap from control cells before adsorption of the synthetase to poly(I) · poly(C)-paper, the yield of 2-5A after incubation was proportional to the amount of interferon cell sap used. The levels of ATP used were not limiting. Optimum conditions for synthesis of 2-5A were identical with the chick oviduct, reticulocyte or interferon enzyme bound to poly(I) · poly(C)-paper. Therefore, these conditions

were used throughout the survey of synthetase levels in different cells and tissues described in Table 1.

2-5A synthetase was detected readily in all the mammalian extracts tested, but the amount of enzyme activity varied more than 1,000-fold (Table 1). It was lowest in MRC5 cells in which there was little change in level with passage number, with the possible exception of a significant decrease at passage 55 just before senescence at passage 57. There was slightly more enzyme in pig lymphocytes, with or without stimulation by phytohaemagglutinin. Significantly higher levels were obtained in mouse erythroleukaemia (Friend) and in human lymphoblastoid (Namalva) cells. The fact that the different Friend cell lines F4N, F4N+2 and F4N+ (ref. 13), have different levels is

Table 1 2-5A synthetase levels in a variety of cells and tissues

	Source	Specific activity (pmol 2-5A per A ₂₆₀ per h)
1	Interferon-treated mouse L cells (splitter culture)	600
	Control cells	1
2	Interferon-treated human diploid fibroblasts (ICRF23)	600
	Control cells	10
3	Rabbit reticulocytes	300*
4	Chick oviduct (see Table 2)	5-200
5	†Guinea pig mammary gland:	
	pregnant	70
	lactating	5-50
	2 day-withdrawn	60-80
	4 day-withdrawn	100
6	†Mouse erythroleukaemia (Friend) cells:	
	F4N	10
	F4N+	4
	F4N+2	115
7	†Human lymphoblastoid cells (Namalva)	50
8	Mouse L cells (monolayer) subconfluent to 8-day confluent	0.6-6
9	†Green monkey kidney cells (Vero): subconfluent to 2-day confluent	0.1-1
10	Human diploid fibroblasts (MRC5): passage 37, subconfluent to 6-day confluent	<0.1-0.3
11	†Pig lymphocytes	1.5*
	Phytohaemagglutinin-stimulated	3*
12	† <i>Xenopus laevis</i> :	
	liver	<0.04
	pooled blood cells	<0.04
13	† <i>Drosophila melanogaster</i> :	
	20-h embryos	<0.04
	3rd instar larvae	<0.04
	adult flies	<0.04

Extracts (post-mitochondrial supernatant fractions) were prepared at 0-4°C from packed cells or finely minced tissue which had been frozen at -70°C as described previously⁹ except that the homogenisation buffer contained 0.5% NP40 where indicated (†). (Control experiments showed 0.5% NP40 to be without effect on the assay of the synthetase.) The absorbance of the extract at 260 nm (A₂₆₀) was determined after dilution with 0.4 M NaOH. The synthetase was bound to poly(I)·poly(C)-paper by incubating 100-200 µl of extract with 1 cm² of paper for 1 h at 25°C. The paper was washed thoroughly with 90 mM KCl, 10 mM HEPES, pH 7.5, 1.5 mM magnesium acetate, 7 mM 2-mercaptoethanol, 20% glycerol (v/v). It was incubated for 30 min at 25°C with 1 ml of the same buffer containing 50 mM KCl, and then for 18 h at 30°C with 10-200 µl of this buffer containing 3 mM ATP and 8.5 mM magnesium acetate. The yield of 2-5A was assayed by determining the dilution required for 50% inhibition of protein synthesis in an L-cell-free system programmed with encephalomyocarditis virus RNA, in comparison with a standard preparation of 2-5A assayed in parallel.^{11,15} Specific activities are based on the amount of 2-5A produced per h, in AMP equivalents. Poly(I)·poly(C)-paper (10-20 µg poly(I)·poly(C) per cm²) was prepared by a modification of the method of Alwine *et al.*¹⁶. To a 20×10 cm sheet of diambenzylxymethyl-paper were added 5.0 ml of a mixture of 0.5 ml poly(I)·poly(C) (10 mg ml⁻¹), 0.9 ml of 25 mM sodium phosphate buffer, pH 6.0 and 3.6 ml dimethyl sulphoxide. After incubation overnight at room temperature, the following mixture was added to allow the denatured RNA to rehybridise: 3 ml bovine serum albumin (2 mg ml⁻¹, pretreated with 0.1% diethylpyrocarbonate for 1 h at room temperature), 1.5 ml 10% SDS, 25 ml 2×SSC (300 mM NaCl, 30 mM trisodium citrate), 30 ml formamide, 8.5 µl poly C (5 mg ml⁻¹). After 24 h at room temperature with gentle shaking, the paper was washed thoroughly 3 times with 2×SSC, blotted dry and stored at -70°C. Interferon treatment of mouse L cells was as described previously²; treatment of the human diploid fibroblasts (ICRF23) was for 24 h at 37°C with 10⁵ units ml⁻¹.

* The A₂₆₀ of these extracts was not determined and was assumed to be 100 for the calculation of specific activity. Values of 20 to 160 were determined for the remainder of the samples.

interesting but its significance is not known. More interestingly, the level of enzyme in chick oviducts varied with the time of withdrawal from stimulation by oestrogen (see below and Table 2). A preliminary search for a similar phenomenon in mammary glands from lactating guinea pigs, which involute on removal of the young, has yielded equivocal results so far (R. K. Craig, G.R.S., R.E.B. and I.M.K., unpublished). Finally, in a total of six experiments, enzyme levels were compared in subconfluent and confluent monolayers of L, Vero and MRC5 cells. The level of enzyme in confluent cells increased very gradually for up to 8 d.

In the experiments with chick oviducts, despite some individual variations (see Table 2 legend), the same trend was seen in multiple assays of extracts from five different sets of oviducts. It seems reasonable to conclude, therefore, that the assayable enzyme remains relatively low in the first 24 h after hormone withdrawal and increases gradually thereafter, to reach final levels about 10-fold higher, approaching those in reticulocytes or interferon-treated cells (Table 1). Control experiments indicated that the differences observed with extracts made as described in Table 2 probably reflect changes in the level of 2-5A synthetase rather than changes in the levels of an antagonist or degradative enzyme. For example, a dominant inhibitor was not detected in mixing experiments. In addition, synthesis of 2-5A was linear for up to 40 h with paper-bound enzyme from oviducts early (1 h) or late (10 d) after withdrawal from hormone, and added 2-5A was equally stable in either case.

The inhibitor of protein synthesis generated by incubation of the enzyme bound to poly(I)·poly(C)-paper was not characterised in most of the experiments shown in Table 1. However, the product from chick oviducts was radioactively labelled¹¹ and characterised as 2-5A by thin-layer chromatography, analysis on DEAE-cellulose in the presence of 7M urea^{4,7}, and high pressure liquid chromatography. It also had the same specific biological activity as mouse or rabbit reticulocyte 2-5A in inhibiting cell-free protein synthesis.

These results demonstrate the wide distribution and variation in level of detectable 2-5A synthetase activity in a variety of cells and tissues. Small differences in activity are probably not significant with the biological assay used, but it seems improbable that the large differences observed in Tables 1 and 2 are trivial. The relationship between the increase in 2-5A synthetase and the decrease in the proportion of tubular gland cells which accompanies long-term withdrawal of the oviduct from oestrogen stimulation is not known, but the enhanced level of synthetase suggests a possible involvement of the 2-5A-dependent nuclease in the regression of this tissue. A role for the 2-5A system in the rapid degradation of ovalbumin mRNA that quickly follows withdrawal of oestrogen (ref. 14 and W.J.D. and R.T.S., unpublished) is also possible, despite the apparently low levels of 2-5A synthetase at this time (Table 2). Note that here we are assaying only one component of the 2-5A system and we have no means of knowing what levels would be rate limiting in different conditions in the intact cells. Moreover, we cannot yet be certain that pre-activated 2-5A synthetase already bound to daRNA (or alternative activator) might not be sequestered and unavailable to the assay used, that is, here we may be assaying potentially active rather than total, or active, enzyme. 2-5A has a short half life in chick and L-cell-free systems, but saturates the activatable nuclease at very low concentrations, below 10 nM (ref. 9, B.R.G. Williams and I.M.K., unpublished data). Accordingly, to understand the operation of the 2-5A system fully it will also be necessary to determine the nature and level of the (daRNA) activator of the synthetase, whether the level of 2-5A sensitive nuclease varies, what intracellular levels of 2-5A are achieved and how these levels are maintained by a balance of synthesis and degradation in different tissues in different conditions. This last point will require the development of a convenient quantitative assay for 2-5A capable of detecting physiological concentrations (< nanomolar) in extracts of cells. Meanwhile, despite the uncertainties outlined above in the

Table 2 Effect of withdrawal of oestrogen stimulation or 2-5A synthetase activity in chick oviducts

10 d-withdrawn	134	130

Extracts prepared without NP40 from chick oviducts pre-frozen at -70°C were assayed for 2-5A synthetase by the method given in Table 1, scaled down 10-fold. Oestrogen stimulation of 5 to 7 day-old chicks and withdrawal after 14 days were accomplished by subcutaneous implantation and removal of diethylstilbestrol-impregnated silastic pellets (W.J.D. and R.T.S., unpublished). There was some variability in the values obtained in different experiments: for example, 6 different 10 day-withdrawn oviducts yielded values of 85, 88, 120, 130, 134 and 200. The only extensive variation was obtained with five fully stimulated oviducts, which gave values of 1.5, 5.5, 12, 15 and 290. The reason for this variability is not known, although the one very high value might reflect an elevated interferon level due to an undiagnosed virus infection.

Interpretation of the levels of synthetase detected, the very different levels observed, whether they reflect total or only potentially active enzyme, are of interest and indicate a wider significance for the 2-5A system than simply in the antiviral action of interferon. Taken together, the function of 2-5A in activating a nuclease which degrades mRNA, the widespread occurrence of 2-5A synthetase, the high levels of this enzyme in highly differentiated cells where mRNA degradation may have played a part in preparing the cell for specialised function¹² and the increase in the level of synthetase in some situations strongly suggest that the 2-5A system may have an important regulatory function in processes such as maintenance of cell stasis, tissue regression and differentiation.

We thank Drs J. Taylor and T. Sreevalsan, R. K. Craig, H. Eisen, M. Johnston, M. J. Crumpton, I. Buchanan, G. Dimitriadis and D. Ish Horowitz for the ICRF23 cells, guinea pig mammary glands, Friend and Namalva cells, pig lymphocytes, MRC5 cells and the *Xenopus* and *Drosophila* tissues, respectively.

'Freezing' of Ca-regulated conformation of reconstituted thin filament of skeletal muscle by glutaraldehyde

REGULATION of skeletal muscle contraction by calcium ions is mediated by the troponin-tropomyosin system located in the groove of actin double strands¹. Acting with tropomyosin, troponin depresses the ability of the actin filament to interact with the myosin molecule in the presence of ATP. Some structural changes in the thin filament associated with this depression have been detected by physical techniques²⁻⁸. When the actin filament is cross-linked with glutaraldehyde, it retains the ability to activate myosin ATPase⁹, and troponin and tropomyosin can no longer exert their regulatory effect on these cross-linked or 'frozen' actin filaments¹⁰. Using glutaraldehyde as cross-linking agent we have now been able to 'freeze' the activated (presence of calcium) and depressed (absence) states of the actin filament induced by the troponin-tropomyosin system: this suggests that the structural changes detected using physical methods are essential for regulation by calcium.

Reconstituted thin filament, composed of 0.25 mg ml⁻¹ troponin, 0.22 mg ml⁻¹ tropomyosin and 1 mg ml⁻¹ actin from rabbit back muscle, was incubated with 0.1% glutaraldehyde (Sigma) in a solution containing 0.1 M KCl, 3 mM MgCl₂ and 50 mM HEPES (pH 7.2) for 7 min at 25 °C in the presence or absence of calcium ions. The cross-linking reaction was terminated by adding KSCN to a final concentration of 50 mM, and the resulting solution containing cross-linked thin filaments was dialysed against 0.1 M KCl containing 3 mM MgCl₂ and 20 mM Tris-HCl (pH 7.6).

Fig. 1 SDS-polyacrylamide gel electrophoresis¹⁵ of the reconstituted thin filament before (a) and after (b) cross-linking with glutaraldehyde.

Table 1 Myosin ATPase activities activated by cross-linked thin filament

Type of thin filament	ATPase ($\mu\text{mol Pi per min per mg}$)	
	$10^{-7} \text{ M Ca}^{2+}$	$1.3 \times 10^{-5} \text{ M Ca}^{2+}$
Control	0.025	0.112
Cross-linked in the absence of Ca^{2+}	0.042	0.039
Cross-linked in the presence of Ca^{2+}	0.145	0.150

ATPase was assayed at 25°C in a solution containing 0.2 mg ml^{-1} myosin, 0.2 mg ml^{-1} thin filament, 0.1 M KCl , 3 mM MgCl_2 , $20 \text{ mM Tris-maleate}$ ($\text{pH } 6.8$) and 1 mM ATP . Ca^{2+} concentration shown corresponds to the presence of 0.1 mM EGTA alone (10^{-7} M) or the presence of 0.1 mM EGTA containing 0.095 mM CaCl_2 ($1.3 \times 10^{-5} \text{ M}$). ATPase activity was determined by the method of Youngburg and Youngburg¹⁶.

On SDS gels, most proteins of the cross-linked thin filament did not enter the acrylamide matrix, indicating that a considerable degree of intermolecular cross-linking had occurred (Fig. 1). However, under the electron microscope no differences in filamentous features could be seen between the thin filament before and after cross-linking.

As shown in Table 1, the reconstituted thin filament cross-linked in the presence of the calcium ion (that is, in the activated state) did not show the depression of actin-activated myosin ATPase even in the absence of the calcium ion, whereas the filament cross-linked in the absence of the calcium ion (in the depressed state) showed only a low level of activation of myosin ATPase even in the presence of calcium ion. In each case, the ATPase activity was not influenced by the calcium ion.

Thus cross-linking with glutaraldehyde can 'freeze' the structure of the thin filament in a specified functional state. Glutaraldehyde may therefore be useful as an aid in the structural analysis of the thin filament⁸. When dimethylsuberimide dihydrochloride was used as cross-linking agent in place of glutaraldehyde, extensive cross-linking of the thin filament was observed but the interaction of the resulting thin filament with myosin was still regulated by calcium ions.

The method described here will be of wide application, and has already provided evidence to show that gizzard muscle regulation¹¹ is actin-linked, as has been asserted by Ebashi *et al.*¹²⁻¹⁴.

Movement of myosin heads during a heart beat

X-RAY diffraction studies of heart muscle undergoing cyclic contractions have shown that the myosin heads are transferred from the vicinity of the thick filaments to that of the thin filaments as the muscle passes from the diastolic (relaxed) to the systolic (contracted) state^{1,2}. We have now followed the time course of this transfer using a fast X-ray diffraction technique and found that the transfer occurs almost in parallel with tension development.

A papillary muscle was isolated from the right ventricle of a canine heart and cross-perfused with the arterial blood of a donor dog³. A branch of the arterial tubing was used to drip warm blood on to the surface of the muscle to keep the temperature of the muscle at about 37°C . The muscle was held isometrically at the optimal length (L_{max}) and was stimulated once a second with a square pulse of 5-ms duration (for details see ref. 4). The muscle was connected to a tension transducer (Shinko, UL) and mounted vertically in a low-angle camera of the mirror-monochromator type⁵. The X-ray source was a rotating-anode generator (Rigaku FR) operated at 50 kV with a tube current of 70 mA (the size of the focal spot was $1 \times 0.1 \text{ mm}$). The equatorial diffraction pattern from the muscle was recorded with a position-sensitive counter of the triangular-cathode type⁶ at a specimen-to-counter distance of 70 cm. The output of the counter was fed to a memory circuit⁷⁻⁹ which registered separately the signals from 16 different phases during the cardiac cycle. To obtain reasonable photon statistics for each phase the cardiac cycle was repeated 4,000-10,000 times.

The muscle produced a peak tension of $483 \pm 38 \text{ g cm}^{-2}$ at a time $250 \pm 8 \text{ ms}$ after the beginning of the stimulus (mean $\pm$ s.e.m., number of muscles = 5). The diffraction pattern showed the 1, 0 and 1, 1 equatorial reflections from the hexagonal array of the myofilaments (Fig. 1). We measured the integrated intensities of these reflections and calculated the intensity ratio ($I_{1,0}/I_{1,1}$). On contraction the 1, 0 intensity decreased and the 1, 1 intensity increased, so that the ratio $I_{1,0}/I_{1,1}$ decreased.

Fig. 1 Equatorial intensity distribution (right half only) of the X rays scattered by a canine papillary muscle in a 62.5-ms period during the diastolic phase. Thin papillary muscles ($0.65\text{--}1.2 \text{ mm}$ thick) were chosen in order to avoid high background scatter. The muscles were capable of contracting more than 20,000 times with little decline of peak tension⁴. Approximately 4,800 contractions were needed for recording the intensity distribution. The intensities of the 1, 0 and 1, 1 reflections from the hexagonal myofilament lattice were obtained by measuring the area under the peaks; the background level under each peak was drawn in by eye.

Fig. 2 Changes in the equatorial intensity ratio ($I_{L,0}/I_{L,1}$) in a papillary muscle during the cardiac cycle. The 1-s cycle was divided into 16 phases, and the ratio was measured for each phase; the first 250 ms of the cycle was divided into eight 31.25-ms phases, the following 250 ms into four 62.5-ms phases, and the last 500 ms into four 125-ms phases. Note that, as the contraction was cyclic, the last period of measurement (875–1,000 ms after the beginning of the stimulus) was followed immediately by the first period (0–31.25 ms after the beginning of the stimulus). The same set of diffraction patterns was measured by three different people who made their own estimation of the background level (see legend to Fig. 1); symbols (○, ●, □) represent the measurements by different people. The tension record was obtained by averaging 10,000 contractions with a multichannel analyser⁹. The cross-sectional area of the muscle at its middle was 0.045 cm².

Figure 2 shows that the time course of the change in intensity ratio was an approximate mirror image of the tension curve; the ratio reached the minimum value of 0.74 ± 0.06 ($n = 5$) at approximately the same time as the peak tension.

The observed decrease in the intensity ratio was caused partly by radial transfer of myosin heads from the thick to the thin filaments and also by slight shortening of sarcomeres; although the muscle was held isometrically, the sarcomeres in the middle of the muscle became about 10% shorter at the peak of contraction². Figure 3 shows the result of an experiment in which we assessed the contribution of the sarcomere shortening. First we obtained an intensity-ratio time-course with a muscle length of L_{max} (solid line). Then we repeated the measurements (dotted line) on the same muscle with a muscle length of $0.9L_{max}$ so that the sarcomeres were already 10% shorter in the diastolic phase (and therefore about 20% shorter at the peak of contraction). If the sarcomere length had stayed constant (at the length which was attained at the peak of contraction for the first set of measurements) throughout the cardiac cycle, the intensity ratio would have changed in the following manner: (1) the ratio would have corresponded to a point on the dotted line at the beginning of the cycle, and moved toward the solid line as the tension developed; (2) the ratio would have reached the solid line at the peak of tension; the minimum ratio at a constant sarcomere length would have been found near the minimum of the solid line; and (3) the ratio would have moved toward the dotted line during the falling phase of tension, reaching the dotted line when the tension reached the steady diastolic level. Such an imaginary curve would represent more correctly the radial transfer of myosin heads; a decrease in the ratio at a constant sarcomere length represents an increase in the number of heads in the vicinity of the thin filaments^{10,11}. Our results suggest that the number reaches a maximum approximately at the time of peak tension, at ~250 ms after the stimulus at 37°C. This is much slower than in skeletal muscle in which the number reaches a maximum within 70 ms after the stimulus at 0°C and even earlier at higher temperature^{9,12} (the peak tension in skeletal muscle occurs 150–160 ms after stimulus at 0°C). The slow

transfer of myosin heads in heart muscle may be the basis of the slow development of the active state in heart muscle¹³.

The maximum intensity ratio obtained during the diastolic phase was 1.72 ± 0.09 ($n = 5$) at L_{max} , and smaller at $0.9L_{max}$ (Fig. 3). It is known that a quiescent heart muscle at $0.9L_{max}$ gives an intensity ratio of 3.07 (ref. 1) which is considerably greater than the maximum ratios obtained in the present study. This indicates that, during the cardiac cycle, the myosin heads as a whole never go into the 'quiescent' state; there is always a considerable number of heads remaining in the vicinity of the thin filaments during the diastolic phase. However, these myosin heads are unlikely to be producing significant force during the diastolic phase as a previous study² has shown that a change in the number of 'remaining' myosin heads is not accompanied by a change in the diastolic tension.

It is of interest to know how the behaviour of myosin heads during the cardiac cycle is affected by the physiological means used to change the size and the time course of tension development. We studied the effect on the intensity ratio of repetitive stimulation with paired pulses; this type of stimulation increases the peak tension and shortens the time from stimulus to the peak tension¹⁴. A muscle was first stimulated once a second with single pulses. Then the same muscle was stimulated every second with a pair of pulses to cause stronger contractions. The interval between the pair of pulses was set at 270 ms to produce maximal potentiation. The time course of the intensity ratio for the two patterns of stimulation are compared in Fig. 4. When stimuli were changed from single to paired pulses, the muscle had to be stretched slightly in order to re-adjust its length of L_{max} ; the internal shortening of sarcomeres was enhanced by the increased tension. This re-adjustment allowed us to compare the minimum intensity ratios, which were obtained at the time of peak tension both with single and paired pulses, at approximately the same sarcomere length. The minimum ratio was smaller with paired pulses than with single pulses, suggesting that paired-pulse stimulation increases the number of myosin heads found in the vicinity of the thin filaments at the peak of contraction. This is likely to be the basis of the tension increase caused by paired pulses. The intensity ratios in the diastolic

Fig. 3 The intensity ratios obtained from the same muscle at different muscle lengths, L_{max} (filled circles and solid line) and $0.9L_{max}$ (open circles and dotted line). The 1-s cardiac cycle was divided into 16 phases of 62.5-ms duration. The tension records are averages of all the contractions needed for recording diffraction patterns at L_{max} and $0.9L_{max}$. The cross-sectional area of the muscle at L_{max} was 0.084 cm².

Fig. 4 The intensity ratios obtained from the same muscle contracting at the same frequency (1 s^{-1}) but with different types of stimuli; single pulses (○) and paired pulses (●). The interval between the pair of pulses (270 ms) was in the range where maximal potentiation was obtained. The tension records are averages of all the contractions needed for recording diffraction patterns with single pulses (dotted line) and paired pulses (solid line). The cross-sectional area of the muscle was 0.023 cm^2 .

phase were also smaller with paired pulses than with single pulses. This decrease in the ratio was not attributable to the re-adjustment of muscle length as stretching a muscle would be expected to increase the ratio (Fig. 3). Therefore, our observation suggests that the number of myosin heads remaining in the vicinity of the thin filaments during the diastolic phase is also increased by paired-pulse stimulation.

Tn554—a site-specific repressor-controlled transposon in *Staphylococcus aureus*

PREVIOUS studies have defined a specific element in *Staphylococcus aureus* containing determinants of inducible erythromycin resistance and spectinomycin resistance. This element has many plasmid-like properties^{1,2} but is not associated with detectable extra-chromosomal DNA². The resistances are similar in mechanism to those ordinarily associated with plasmids^{3,4} (J. Davies, personal communication); the element can be transferred by transduction² or transformation to a *rec*⁻ recipient with the same efficiency as to a *rec*⁺, and the two determinants show essentially 100% linkage in genetic transfer. Consequently, this linkage group has previously been referred to as a 'pseudoplasmid' (ref. 2). On the basis of the results presented here, we suggest that this pseudoplasmid is actually the prototype of a new class of transposon, which functions by means of a highly efficient, repressor-controlled, site-specific integration-excision mechanism. This transposon, designated Tn554 (EmSp), can be most easily envisaged as a prophage-like element that lacks replicative autonomy and other vegetative phage functions.

Table 1 lists the *S. aureus* strains used. Transduction and transformation were carried out by standard methods^{5,6} whole-cell and plasmid DNA were isolated and analysed by standard methods^{6,7}.

Initial transformation mapping results indicated that Tn554 is weakly (co-transformation frequency of $\leq 1\%$) but definitely linked to the chromosomal *tetr* (tetracycline-minocycline resistance) locus previously mapped by Pattee and Neveln⁶. Concurrently, mapping of a series of chromosomal insertions of a different transposon, Tn551 (ref. 8), suggested that one of these, $\Omega 34$, was located at a site very near to that of Tn554 (ref. 9). Accordingly, we carried out a series of transductions to test for linkage between the two, and found that Tn554 and $\Omega 34$ are indeed very closely linked (Table 2). Somewhat inconveniently, Tn551, first found on plasmid p1258 (ref. 8), also encodes erythromycin resistance (in this case, constitutive). Its properties are similar to those of the various *Escherichia coli* transposons¹⁰: it translocates with a frequency of about 10^{-4} per donor genome and inserts at many different chromosomal and

Fig. 1. Possible mechanisms for Tn554 integration. Thin lines represent chromosomal sequences; hatched bar represents the $\Omega 34$ insertion of Tn551; solid bar represents Tn554; open blocks represent the putative attachment site of Tn554; dashed lines represent possible homologous crossovers, resulting in the insertion of the entire region ($a + c$), of Tn551 only ($a + b$), or of Tn554 only ($b + c$). In addition, Tn554 can evidently excise and insert independently; this is presumably its primary mode of transfer to a *rec* recipient.

* Key: Ω , insertion; Δ , deletion; $\rightarrow$, transfer

plasmid sites. Although its transposition is *rec*-independent, it cannot be transduced at a detectable frequency from a chromosomal site to a *rec*⁻ recipient². This is presumably merely a question of multiplied probabilities; a transposition frequency of 10^{-4} coupled with a transduction frequency of 10^{-6} – 10^{-7} results in a combined probability of $<10^{-10}$, which is well below the limits of detectability in this system.

Transduction with RN2784, carrying Ω 34 and an Em^r mutant of Tn554, as donor, revealed 50% linkage between Tn554 and Ω 34 when selection was for the Tn551 Em^r determinant, but only 10% when selection was for the Tn554 Sp^r determinant. This asymmetry could either be due to transductional polarity (involving the specificity of transducing fragment ends)¹¹, or to specific excision–insertion of Tn554, which inevitably disrupts the linkage with the Ω 34 locus. Two lines of evidence support the latter interpretation. In a similar experiment carried out by transformation, the same asymmetry was obtained; and in a transductional cross using the same donor but a *rec*⁻ recipient, no co-transduction of Tn554 and Ω 34 was observed; all of 315 Sp^r transductants were Em^r and no Em^r transductants were obtained. Further, in these experiments, the entire Tn554 *ermA4* element was acquired; all of five Em^rSp^r transductants tested reverted to Em^r (inducible) at the same frequency as the original Tn554 *ermA4*.

On the basis of these results, it seemed possible that specific excision–insertion of Tn554 was responsible for its transfer to the *rec*⁻ recipient. Two other possibilities were considered: (1) that it was maintained as a plasmid in the *rec*⁻ strain, and (2) that it carried the *rec*⁺ allele, enabling it to recombine into the chromosome. These were ruled out by a failure to demonstrate plasmid DNA in two different *rec*⁻ transductants and by a demonstration that these were unable to accept the chromosomal *tna* marker and were, therefore, still *rec*⁻. Because transfer of Tn554 to a *rec*⁺ recipient could involve either homologous recombination or specific insertion, whereas transfer to a *rec*⁻ could involve only the latter, the site specificity of the putative insertion process was tested with several independent *rec*⁻ transductants. Tn554 was mapped in the *rec*⁻ by scoring for transductional displacement of Tn551 in *rec*⁺ recipients containing Ω 34 in comparison with Ω 5, a Tn551 insertion unlinked to Tn554 by transduction. Five different *rec*⁻ Tn554 strains each gave about 8% displacement of Ω 34 but no detectable displacement of Ω 5, consistent with insertion of Tn554 in the *rec*⁻ chromosome at the same location as in the *rec*⁺ (Table 2).

The high frequency of excision and insertion required to account for the efficient transfer of Tn554 to the *rec*⁻ strain, and the very great stability of the element once established, suggested that excision, at least, is controlled by a transposon-specific repressor. If so, the high frequency of transfer to the *rec*⁻ would be analogous to zygotic induction, as the recipient would lack repressor; that is, the element would excise from the transducing

fragment on which it was injected by the phage, and then insert by site-specific recombination into the chromosome. A probable mechanism for this sequence of events is that proposed originally by Campbell¹² to account for the excision and insertion of coliphage λ (Fig. 1). The excision step could, of course, occur in the donor during phage maturation, in which case one need not postulate a repressor to account for the results described so far. In any case, as a preliminary test for the presence of a repressor, we compared the transduction frequency of Tn554 *ermI1 spc-1* to recipient strains with and without Tn554 *ermA5* and found that the presence of the Tn554 derivative in the recipient markedly inhibited super-transduction. This inhibition was greater in the *rec*⁻ recipient (about 100-fold) than in the *rec*⁺ (about 10-fold), which is expected regardless of the mechanism of inhibition, as recombinational displacement occurs in the *rec*⁺ but not in the *rec*⁻. Although this result is consistent with the existence of a repressor of excision or of

* Transductants per plaque-forming unit of phage (PFU) were approximately 10^{-6} for Tn551 donors and 10^{-5} to 10^{-6} for Tn554 donors

Figures in parentheses represent numbers of transductants scored for this value. Key. Em^r = erythromycin resistant, Sp^r = spectinomycin resistant; Em^s = erythromycin sensitive; Sp^s = spectinomycin sensitive.

Fig. 2 Agarose (0.7%) gel electrophoresis of plasmids digested with *Bam*HI and *Bgl*II. In each pair, the digest of the plasmid carrying the Tn554 insertion is on the left. Slot 1 = pRN4166 cut with *Bam*HI; slot 2 = pRN1107 cut with *Bam*HI; slot 3 = pRN4166 cut with *Bgl*II; slot 4 = pRN1107 cut with *Bgl*II. Slot 5 contains phage λ *Eco*RI fragments. Note the loss of a 2.6-kilobase pair *Bgl*II fragment (slot 4) and the appearance of two new fragments, one of which co-migrates with a fragment already present, and thus appears as a doublet (slot 3).

excision-insertion, an alternative possibility is direct interference by the resident transposon with the integration of the superinfecting one, through insertional disruption of the putative attachment site (Fig. 1).

To distinguish between these two possibilities, it was necessary to obtain a Tn554 insertion in a secondary site, most conveniently a plasmid. This was initially attempted with a strain carrying a penicillinase plasmid (pI524) plus Tn554 as a donor in a transduction with double selection for the plasmid-linked cadmium resistance (*Cd*^r) and Tn554-linked *Em*^r markers. Although a few doubly resistant transductants were obtained, these were all found to contain the original plasmid and a chromosomal Tn554. In retrospect, this is the expected result if, indeed, there is zygotic induction of Tn554 transposition. As this result suggested that Tn554 could insert into the plasmid, we adopted the approach of transducing Tn554 *ermI1 spc-1* into a *rec*⁻ recipient containing Tn554 *ermA5* in the chromosome (as the source of the putative repressor), and a plasmid, pRN1107, as a secondary target for the transposon. The plasmid used was a pI524 derivative with a thermosensitive replication defect (*Tsr*)¹³, permitting the scoring of plasmid linkage by testing for co-elimination during growth at 43°C, the restrictive temperature. As before, there was a 100-fold reduction of Tn554 *ermI1 spc-1* transduction frequency in these conditions, but in one of 10 *Em*^r transductants obtained, the incoming Tn554 *ermI1 spc-1* was co-eliminated with cadmium resistance during growth at 43°C, and was therefore presumed to have inserted into the plasmid. The apparent plasmid linkage was confirmed by

agarose gel electrophoresis after digestion with restriction endonucleases. These results revealed a 6.2-kilobase insertion in the plasmid carrying Tn554 (Fig. 2).

Having obtained a plasmid insertion of Tn554 *ermI1 spc-1*, we were able to test more directly for the action of a repressor. This was accomplished by further transduction of this plasmid, pRN4166, into two new recipient strains, one carrying a chromosomal Tn554 *ermA5* insertion (RN2896), the other not (RN27). In this experiment, *Cd*^r (plasmid-positive) transductants were tested first for the presence of the Tn554 *ermI1 spc-1* *Em*^r marker and then, by temperature-induced curing, for the linkage of Tn554 *ermI1 spc-1* to the plasmid.

The results of this test indicated that the plasmid and the inserted transposon were co-transduced with a frequency of about 50% (the reason for this is now under investigation); among the co-transductants obtained, the linkage between the plasmid and the transposon was disrupted in all of 10 *Cd*^r*Em*^r clones derived from the recipient lacking a chromosomal Tn554 and was preserved in all of 10 derived from the recipient containing one. Here again, the linkage was evaluated by temperature-induced curing of the plasmid.

This result is consistent with a repressor of Tn554 excision encoded by the transposon itself. If site-specific interference with insertion were responsible for the inhibition of transduction described above, then the chromosomal Tn554 element should not have had any effect on excision of the incoming transposon from the plasmid, only on its subsequent insertion into the chromosome. It is conceivable, however, that excision and insertion are integrated processes, so that if insertion is blocked, excision is automatically blocked also. We consider this unlikely because excision regenerates an intact plasmid; this suggests that Tn554 is excised in the double-stranded configuration.

The simplest mechanism in which double-stranded excision is coupled with restoration of continuity is that proposed by Campbell for the excision-insertion of coliphage λ (ref. 12). In this mechanism, involving the generation of a circular intermediate by a site-specific intramolecular crossover, excision occurs independently of the fate of the excised molecule. If this is, in fact, the correct interpretation for Tn554 transposition, then it is the first example of transposition occurring by the Campbell mechanism. We note that other transposons, particularly Tn9(*Cm*), also show *rec*-independent excision with preservation of the carrier genome, but there is no evidence for a Tn9 repressor, and the excised transposon is nearly always lost rather than reinserted at another site¹⁴.

Figure 1 is a summary of the postulated mechanisms of transfer and insertion of Tn554. Experiments are now in progress with the aim of confirming the existence of a repressor and analysing the excision-insertion process it controls.

This investigation was supported by research grants (to R.P.N.) from the NIH (GM14372) and the NSF (PCM77-25976). Erythromycin was donated by Eli Lilly, spectinomycin by Upjohn, and tetracycline by Pfizer.

Announcing

Cold Spring Harbor Symposia On Quantitative Biology Volume XLIII DNA: Replication and Recombination

Marking the 25th anniversary of the discovery of the double-helix model of DNA structure, this Symposium volume profoundly illustrates the coming together of the worlds of genetics and biochemistry that has occurred over the last quarter-century.

The 152 papers contained in this massive two-book work sum up the tremendous strides made in the areas of replication of genetic material and reassortment of genetic information through general and specialized recombination. The explosive developments in the areas of gene cloning and transposable elements are presented, as well as the climax of the enzymology of DNA replication using small replicons as models.

This compendium, like its predecessors, will be a basic resource tool for years to come.

CONTENTS

Introduction: Aspects of DNA replication
(Kornberg)

DNA Unwinding

Wave propagation in DNA (Sobell),
Gene-V-protein-DNA complex (McPherson),
Biblical and superhelical DNA (Wang), DNA
gyrase (Gellert), *E. coli* DNA gyrase (Peebles),
Regulation and specificity of unwinding enzyme
(Champoux), Replication with fd gene-II protein
(Geider), DNA helicases (Kuhn)

Replication Origins

Replication of ColEI-type plasmids (Backman),
Nucleotide sequence of pBR322 (Satchliffe),
Plasmid-encoded replication factors (Kotter),
Essential replication regions of F and ColEI
(Kahn), Plasmid replication functions (Timmis),
Cloning of R6K replication regions (Crosa),
Genetics and physiology of *oriC* (von
Meyenburg), *E. coli* replication origin (Hirota),
Nucleotide sequence of the *E. coli* replication
origin (Messer), Control of λ DNA replication
(Purth), Lambdaoid origins (Moore), Replicator
(Hobom), Origin of replication of mitochondrial
DNA (Attardi), Replication origin of mtDNA
(Kokke)

Priming and Okazaki Fragments

RNA primer in discontinuous DNA replication
(Okazaki), Excision repair of uracil in DNA
(Lehman), Okazaki pieces on cellophane discs
(Thomas), Uracil incorporation into nascent DNA
(Tamanoi), Nonnascent DNA the size of Okazaki
fragments (Desbardi), mtDNA replication
(Bogenhagen), DNA synthesis in animal cells
(Taeng), Initiator RNA synthesis (Reichard), 5'
ends of nascent DNA chains (Werner)

Replication of Small Phages and Plasmids

Phage SS $\rightarrow$ RF replication (Meyer), ϕ X174 RF
DNA replication (Eisenberg), Replication
proteins of *E. coli* (Wickner), Replication of
 ϕ X174 DNA in vitro (Sumida-Yusumoto),
Cleavage site of ϕ X gene-A protein (van
Manafeld), Activities of *rep* protein (Duguet),
DNA-dependent ATPases (Richt),
Single-stranded phage DNA replication (Sims),
G4 DNA replication (Godson), M13 replication
origin (Suggs), ϕ 1 DNA replication in vivo
(Horuchi), Origins in bacteriophage fd (Schaller),
ColEI DNA synthesis by purified enzymes (Itoh),
Replication of plasmid R1 (Gustafsson)

Replication of Large Phages and Bacteria

Replication of bacteriophage T7 DNA
(Richardson), Cloning and recombination in T7
(Campbell), Bacteriophage T7 DNA primase
(Hillenbrand), Partial replication of T7⁺ DNA
(Burek), In vitro T4 DNA replication (Liu), DNA

replication by bacteriophage T4 proteins (Silver),
T4 DNA replication: DNA-delay proteins
(Huang), T4 DNA replication and recombination
(Mong), Late T4 DNA pool (Huichinson),
Replication of ϕ 29 DNA (Ito), *recA*-Dependent
DNA replication (Lark), A *dnaB*-analog protein
of phage P1 (Seubster), *E. coli dnaB* protein and
initiation (Fujimura), Terminus of *E. coli*
(Kuempel), Organization of the origin region of
the chromosome (Yoshikawa)

Replication of Eukaryotic DNA

Prereplicative phase of yeast (Edwards), A
stimulatory factor for DNA polymerase (Chang),
A multienzyme system for DNA replication
(Benbow), Generalized genetic recombination
DNA supercoiling (Tocchini-Valentini),
Properties of human DNA polymerases α and β
(Korn), Functions of DNA polymerases α , β , and
 γ (Hubscher), tRNA recognition by reverse
transcriptase (Anaya), DPB and DNA-dependent
ATPase from mammalian cells (Cottrich), Ap, A
ingers replication (Grummi)

Replication of Eukaryotic DNA Viruses

Binding at the origin (Tjian), *ori* mutants of SV40
(Shortle), Site-directed mutagenesis (Weber),
SV40 chromosome replication (DePamphilis),
Enzymes and SV40 chromosomes (Taubota),
Mammalian replication factors (Oto), SV40
excision (Botchan), Replicating adenovirus DNA
molecules (Kelly), Adenovirus DNA replication
(Sullivan), Covalent DNA-protein complexes
(Coombs), Adenovirus DNA replication (Green),
Adenovirus DNA replication in vitro (Horwitz),
AAV DNA replication (Berns), Vaccinia DNA
replication (Esteban), Mutant HSV DNA
synthesis in vitro (Francke), Herpes simplex virus
DNA (Rozzman), Recombination in HSV
(Wilkie)

Replication of RNA Tumor Viruses

Replication of Moloney leukemia virus
(Haseltine), Retrovirus (Varmus), RNA tumor
virus DNA intermediates (Taylor), Reverse
transcription (Baltimore), Integration and possible
transduction by retroviruses (Steffen)

Recombination Functions and Repair

Mutagenesis by SOS inducers (Witkin), Role of
recF in repair (Clark), Mutagenesis and
repair-enhancing plasmid (Walker), Induction of
prophages and SOS functions (Onishi), Properties
of *recA* protein (Ogawa), Activity of *recA* protein
(Roberts), Fidelity of DNA synthesis (Loeb), A
mutator DNA polymerase (Egler), Replication
fidelity (Radman), DNA repair (Grossman)

General Recombination

Branch migration in recombination (Werner),
DNA recombination (Potter), Enzymatic
cleavage of D loops (DasGupta), Recombination

in hybrid ColEI DNAs (Shimada),
Heteroduplexes in λ recombinants (Fox),
Recombinant λ DNA formed by *Rec* (Ikeda),
Recombination in bacteriophage T7 (Roeder),
Intermediates in genetic recombination in vitro
(Ogawa), Transduction vs "conjugation" in *E. coli*
(Porter), *EcoB* and *recBC* enzymes
(Rosamond), UV-stimulated recombination
(Waldstein), Chi (Chattoraj), X⁺C sequence
(Smith), *RecA*—Independent recombination at the
chromosome origin (Masters), Homologous
pairing and cutting (Howard-Flanders), Gene
duplication in bacteria (Anderson)

Specialized Recombination of Phages λ and μ

DNA structures in site-specific recombination
(Landy), λ Integrative recombination (Kikuchi),
Integrative recombination of phage λ (Mizumachi),
Differential activity of λ integrase (Enquist),
Recombination host genes (Miller), Regulation
of λ insertion (Heffernan), λ -IS1 interactions
(Shapiro), P1 site-specific recombination
(Sternberg), Site-specific recombination in phages
P1 and P7 (Chesney), μ Integration
(Ljungquist), Site-specific recombination
(Kamp), Mini-Mu (Faelen), The recombinant
plasmid pMB9-Mu ϕ AB ϕ 1 (Gipbart-Gasler)

Insertion Sequences and Transposons

Studies with IS1 and IS4 (Chadwell), Sequence of
IS2-7 and its relation to IS2 (Ghosal), Genome
rearrangements on phage P1 plasmid (Arber),
Regional specificity of Tn ϕ (Weinstock),
Enhanced transposition of Tn9/7 (Tomuch), *r*-det
from R1001 (Chandler), Tn ϕ -promoted
recombination events (Kleckner), Specificity and
control of transposition (Coben), A model for
transposition (Grindley), IS ϕ and Tn9 insertions
(Calos), Sequence analysis of Tn3 (Ohtsubo),
Insertion mutations (Hoffron), Deletion
derivatives of a recombinant plasmid (Federoff)

Recombination Genetics

rDNA in *Tetrahymena* (Yao), Dihydrofolate
reductase gene amplification (Schmle),
Properties of yeast transformation (Hicks),
Conversion of deletions (Raddick), Mismatched
bases and mutability (Holliday), Gene
conversion—Basic recombination event (Fogel),
Gene conversion in *Ascomycetes* (Rossignol)

S&S BA 85 pure nitrocellulose.

Autoradiograms (unretouched, approx. ¼ actual size).

Shown at the top right are unretouched photographs of background-free autoradiograms of labeled RNA or DNA hybridized to single-stranded DNA. They were developed from "Southern" blots and "plaque lifts" using Schleicher & Schuell BA 85 nitrocellulose.

They really make the case for S&S BA 85.

BA 85 succeeds so well because it's *pure* nitrocellulose. This means you get maximum transfer of DNA from gels or plaque lawns. The smaller fragments are not lost. And you're assured of a more complete hybridization with RNA or DNA probes.

For these reasons, S&S BA 85 has become the standard for hybridization studies. When nucleic acid investigators specify "nitrocellulose" they really *mean* pure nitrocellulose — S&S BA 85.

BA 85 is available plain or gridded. And in circles, rolls, squares, strips and full sheets. What more could you ask for? Ask us.

If you're not already using BA 85, you owe it to yourself to try some. Write to S&S on your letterhead and we'll send you a sample in the size you request (up to 15 cm square or 82 mm diameter). Also, S&S has a newsletter on DNA/RNA applications, procedures and products. It's called "Sequences". Ask to be put on the mailing list.

a. DNA fragments which hybridize with a probe that is homologous to nitrogen fixation (*nif*) genes of *Klebsiella pneumoniae*. Prepared by Gerard Riedel, The Biological Laboratories, Harvard University

b. Screens of mouse and human shotgun collections (approx. 25% of original autoradiogram). Prepared by the Blattner and Smithies groups, Laboratory of Genetics, University of Wisconsin. Technique described in the following papers:
1) Blattner, F. R. *et al.* 1978 *Science* 202:1279-1284, 2) Smithies, O. *et al.* 1978 *Science* 202:1284-1289

c. Genome screening of a sea urchin library cloned in Charon 4A bacteriophage. Prepared by D. M. Anderson, R. H. Scheller and J. W. Posakony, Division of Biology, California Institute of Technology.

Detailed descriptions of autoradiograms available on request from S&S

Photos by S. Miller, The Biological Laboratories, Harvard University.

matters arising

Early Precambrian oxygen

FEW of the arguments presented by Towe¹ seem strong enough to build up a case against the photosynthetic origin of Precambrian oxygen as defended, for example, by Margulis *et al.*². Note especially that he does not discuss the relative importance of hydrogen escape compared with recombination after water photolysis although it seems to be a critical issue. To the uninformed, however, one argument might seem decisive: the requirement of oxygen for chlorophyll-*a* biosynthesis. If this has been proved absolute it would be difficult not to admit the existence of some free oxygen before the formation of that molecule necessary for oxygen releasing photosynthesis.

Towe has cited Bogorad³ whose Fig. 1, which summarises chlorophyll-*a* biosynthesis, shows an oxygen-requiring step in the oxidative decarboxylation of coprophenol. This is, however, a common step to every porphyrin (haem as well as chlorophylls and bacteriochlorophylls) which in 1966 had essentially been studied with animal mitochondria. In this text (p. 492) it is mentioned that oxygen cannot be universally required for that reaction as it suppresses bacteriochlorophyll production in the purple non-sulphur bacterium *Rhodospirillum rubrum*. In a more recent treatment of this subject⁴, Bogorad indicated in his Fig. 2 that an alternative to oxygen exists for that step and gives full reference to the work of Tait⁵ who showed that photosynthetic bacteria have both aerobic and anaerobic coprophenolase activity. Since some blue-green algae are clearly able not only to survive but to sustain abundant growth in anaerobic conditions with photosynthesis based on reduced sulphur like some photosynthetic bacteria⁶⁻⁸, those species must be equally able to decarboxylate coprophenol without oxygen. Towe seems to consider that the anaerobic capacity of blue-green algae favours his hypothesis. I would rather consider that it also agrees with the reverse hypothesis, stating like Brock⁹ that "If the bulk of the atmospheric O₂ is indeed of biogenic origin, the organisms first involved in O₂ formation would of course have developed in an anaerobic environment and would have had to be able to live anaerobically".

The argument that in a reducing atmosphere there would be no selection pressure to tap the immense hydrogen resources of water is unconvincing. What would be the difference between

competition for dwindling reductants whether those are consumed by an oxidising atmosphere or prokaryotic photosynthesisers? Anyway even admitting immense resources of H₂S or other reductants which could be used for bacterial photosynthesis, in the competition between organisms, depletion can be a phenomenon localised to some biotic environments.

TOWE REPLIES—Demoulin is disturbed primarily by my statement¹ that unless the molecular oxygen requirement of chlorophyll-*a* had been a later modification, the evolution of this pigment in an anaerobic early Precambrian environment would have been unfavorable. The ability of some extant blue-green algae to sustain abundant growth in reducing conditions certainly implies that they can make the necessary decarboxylation step without free oxygen. Whether or not such anaerobic decarboxylation of chlorophyll-*a* took place in early Precambrian ancestral forms having photosystem I only, is unknown. But if the sequence data of Schwartz and Dayhoff² are correctly interpreted the relevance of this point may be moot. After all, if, as they say, the evolutionary development of aerobic respiration preceded that of photosystem II (and hence oxygenic photosynthesis) the oxygen requirements of chlorophyll-*a* biosynthesis would be of limited significance.

On the other hand, the ability of some modern blue-green algae to thrive in reducing environments while endowed with photosystem II but using photosystem I only³⁻⁵ is certainly not, as Demoulin has asserted also in agreement with the reverse hypothesis; namely, that photosystem II evolved in a reducing environment. The algae in question³ may

survive anaerobic conditions using their photosystem II but they can do so only in the absence of suitable reductants, and tolerance for anaerobic conditions is not the same as dependence on such conditions⁶. There are, it is true, other blue-green algae living today that can grow in a reducing environment⁷ but these require photosystem II at all times. Here the exogenous reductants (H₂S) keep the *pO₂* low rather than to act as primary electron donors for photosystem I. Thus it is important to distinguish between not only the different algal metabolisms but also between the effects of an anaerobic environment and those of an anaerobic-reducing environment. The point is that even today in the presence of reducing conditions, water is not the photosynthetic electron donor of choice for those blue-greens able to choose between photosystem I and II³⁻⁵. There is no such choice for the other modern blue-greens⁷ and, of course, no choice was available to any of the early Precambrian ancestors equipped only with photosystem I, energetically unable to take advantage of the hydrogen resource of water regardless of its immensity and ready availability. Thus I emphasised¹ that "only by removal of reduced substances as potential electron donors for photosystem I would there have been significant pressure (to) develop photosystem II".

Certainly, the effectiveness of atmospheric dissociation is important to the early Precambrian environments, and I stated¹ as much, but there are simply too many debatable assumptions involving the solar constant, water vapour mixing ratios, and, especially, hydrogen sources and sinks, implicit in the calculations to make any answer definitive. Photodissociation cannot be ruled out as a likely source of free oxygen in the early Precambrian.

Effect of prostaglandin E₂ on prostacyclin production by endothelial cells

It has been suggested by Tomasi *et al.*¹ that prostaglandin (PG) E₂ inhibits the synthesis of PGI₂ (prostacyclin) by endothelial cells. This conclusion was based mainly on their observation that the inhibition of platelet aggregation produced by a suspension of isolated hepatic cells (described as "endothelial-rich") was reduced when the hepatic cell suspension was preincubated for 10 min. with 1.5–3 μ M PGE₂. An alternative explanation for this effect, apparently not considered by Tomasi *et al.* is that PGE₂ interferes with the action of PGI₂ rather than its synthesis. We therefore investigated the effects of PGE₂, first on PGI₂ synthesis by aortic endothelial cells, and second, on the inhibition of platelet aggregation caused by exogenous PGI₂.

Production of PGI₂ was measured by radioimmunoassay (RIA) of 6-oxo-PGF_{1 α} (the stable metabolite of PGI₂) in the medium above monolayers of cultured endothelium. In this RIA, 2 μ M PGE₂ showed appreciable cross reactivity, and all samples were therefore treated with 0.3 M KOH in methanol to convert PGE₂ to PGB₂, which showed very little cross reactivity. This treatment did not affect the immunoreactivity of 6-oxo-PGF_{1 α} . The production of 6-oxo-PGF_{1 α} was not reduced by 2 μ M PGE₂ (Table 1); in fact, samples incubated with PGE₂ showed some increase in the amount of immunoreactive 6-oxo-PGF_{1 α} present. Similar increases were, however, measured when 2 μ M PGE₂ was added at the end of the incubation or when 2 μ M PGE₂ was assayed in the same volume of medium alone. Figure 1 shows that as little as 0.1 μ M PGE₂ abolished the inhibition of arachidonic acid-induced platelet aggregation produced by 20 nM PGI₂.

On the basis of these results we conclude that PGE₂, even at the relatively

Fig. 1 Effect of PGE₂ on the inhibition of platelet aggregation caused by PGI₂. Platelet aggregation was measured photometrically in 0.1-ml samples of human citrated platelet-rich plasma⁸. Aggregation was induced by 1 mM arachidonic acid alone (a) or 1 min after the addition of 20 nM PGI₂ (b). 0.1 μ M PGE₂ was added 1 min before arachidonic acid either alone (c) or with 20 nM PGI₂ (d).

high concentration of 2 μ M, does not block PGI₂ synthesis by aortic endothelial cells, but that a lower concentration of PGE₂ can overcome the inhibitory effect of PGI₂ on platelets. The action of PGE₂ may result from competition at the platelet receptor binding PGI₂, although this seems unlikely, as we have evidence that PGE₂ and PGE₁ act at different receptors on the platelet², and PGI₂ apparently acts at the same receptor as PGE₁ (ref. 3). Alternatively, this action could be a consequence of the ability of PGE₂ to facilitate platelet aggregation induced by several stimuli, including products of arachidonate metabolism⁴. Although the hypothesis advanced by Tomasi *et al.*¹ may be valid for the hepatic cell fraction they used (although this still remains to be unequivocally established), it does not apply generally to vascular endothelium.

RIA was from Drs F. Dray and H. Sors, and PGI₂ was from Dr P. L. Walton.

TOMASI ET AL. REPLY—We had considered the possibility that PGE₂ interferes with the PGI₂ receptor, and experiments showing that PGE₂ at the concentrations used (1.5–3.0 μ M) was unable to counteract PGI₂ (2–4 ng ml⁻¹) inhibition in platelet-rich plasma aggregated with sodium arachidonate, were carried out. We have now repeated these experiments with two different sources of PGI₂ with similar findings. However, we were surprised to observe that in the conditions described by Gordon *et al.* (0.1 μ M PGE₂) the results were similar to those reported in their Fig. 1. We agree that this finding cannot be explained by an antagonism of PGE₂ on the PGI₂ receptor. The most likely explanation is that at low doses (0.1 μ M) PGE₂ decreases cyclic AMP levels in platelets¹, counteracting the increase due to PGI₂ (ref. 2) and facilitating aggregation, whereas at higher doses, when PGE₂ has no effect or increases cyclic AMP¹, its action on PGI₂ inhibition is minimal or absent. Thus, in our conditions the effect of PGE₂ must be explained on the basis of a reduction of PGI₂ synthesis. This is supported by experiments showing that our preparations preincubated with PGE₂ and washed twice with buffer were much less effective than controls in inhibiting arachidonate-induced aggregation.

The failure of Gordon *et al.* to observe an effect of PGE₂ on 6-keto-PGF_{1 α} formation may be accounted for: (1) by assuming that their endothelial cells from pig aorta do not contain a PGE₂-sensitive adenylate cyclase (which would be interesting to verify), or (2) by the possibility that PGI₂ is degraded mainly to 6,15-diketo-PGF_{1 α} (ref. 3), which may not be detectable using a 6-keto-PGF_{1 α} antiserum⁴.

We would be surprised if our hypothesis applies generally to vascular endothelium. We consider that the mechanism we have described may operate mainly inside an organ where PGE₂ produced by the major cell population would mediate a control on the endothelial cells lining the organ vasculature⁵.

Endorphins in Mental Health Research

*Edited by Earl Usdin, William E. Bunney Jr, and
Nathan S. Kline*

This collection of papers provides an invaluable
account of the current state of research in this new
field of neuroscience.

Among the many issues discussed are the
biosynthesis and degradation of endorphins, their
function and interaction with other neurotransmitter
and endocrine systems, their localization in brain and
peripheral tissue, their structure, new methods for
their assay, data related to their clinical importance
in man, particularly mental health and their possible
therapeutic utilization in disease states.

Workers in pharmacology and in the neurosciences
generally will find this book indispensable to their
research. The issues it covers are at the very
forefront of concern. They are bound to stimulate a
renewed controversy and further research activity –
both from those already directly involved and from
those who feel that they cannot ignore the
increasing relevance of endorphins to their own
work.

The Latest FASEB Biological Handbook:—

Inbred and Genetically Defined Strains of Laboratory Animals

Part 1: Mouse and Rat

edited by P.L. Altman and Dorothy D. Katz

Inbred and genetically defined strains of laboratory animals are unique research tools: all members of an inbred line have essentially the same genetic constitution. An investigator is able, therefore, to restrict the biological variables affecting an experiment, and to repeat at other times or in other laboratories experiments requiring fine discrimination within a species. The profound insight that genetic expression gives to biological experiments has led to the rapidly increasing use of inbred and genetically defined animals. The difficulties in organizing the information for the different strains and species, and in developing a perspective on the number and availability of such animals, have presented a formidable barrier to those who are not primarily geneticists. The objective in preparing *Inbred And Genetically Defined Strains Of Laboratory Animals* was to organize and present the material in such a way that the range and nature of the data would be immediately accessible to those seeking the information for experimental purposes. Scientists requiring the mouse or rat in their research will find Part 1 of this new data book an essential reference source. Part 2 of this volume, covering hamster, guinea pig, rabbit and chicken is in production.

Contents: MOUSE: Introductory Statements; Inbred and Genetically Defined Strains; Karyology; Development; Epidermis; Biochemical and Endocrine Mutants; Neurology; Immunology; Tumors; Wild Mice; Morphological Traits; Biochemical Polymorphisms; Immunogenetics; Regulatory Systems; RAT: Introductory Statements; Rat Taxonomy; Origin of the Laboratory Rat; Suitability of the Rat for Different Investigations; Inbred and Genetically Defined Strains.

Mechanisms of Osmoregulation in Animals: Maintenance of Cell Volume

edited by R. Gilles, *Institut de Zoologie, Université de Liège, Belgium.*

This book deals with the various mechanisms implicated in cell volume maintenance and regulation. A significant part of it is devoted to the fundamental biophysical and biochemical aspects of these mechanisms, including the state of water in cells and extracellular fluids and transport and metabolism of the various intracellular and blood osmotic effectors. An attempt has also been made to approach important applied aspects of volume regulation in relation to ecology and medicine.

UV-A Biological Effects of Ultraviolet Radiation

by J.A. Parrish and R.R. Anderson, both of *Department of Dermatology, Harvard Medical School, Boston*; F. Urbach, *Skin and Cancer Hospital, Temple University School of Medicine, Philadelphia*, and D. Pitts, *University of Houston*.

Interest in the biological effects of longwave ultraviolet radiation is increasing in all the disciplines which make up the broad field of photobiology. The book originally arose out of a study of the safety of a device used for photopolymerization of fillings in dentistry. The scope has widened to include a consideration of the risks and benefits of electromagnetic radiation between the biologically active short UV and the visible spectrum.

The authors have drawn together results from their own work and from the literature and have placed this information in the perspective of known biological effects of ultraviolet radiation as it affects humans.

Order in Living Organisms: A Systems Analysis of Evolution

by R. Riedl, *Department of Zoology, University of Vienna, Austria*

translated by R.P.S. Jefferies,

British Museum (Natural History), London.

Professor Riedl concentrates on the nature and recognition of order in living organisms. He begins with a discussion on how order can be recognised and makes a fundamental distinction between the law content of a message and the number of instances where the law applies. It is a repetition of law content which makes it possible to recognise order. The author recognises four kinds of order in living organisms depending on the nature of the repeated identity. They are called standard-part order, hierarchy, inter-dependence and traditive inheritance and on this basis he is able to say that, in any recognisable system, certain particular parts will be more readily alterable by selection than others.

Trace Elements and Iron in Human Metabolism

by A.S. Prasad, *Division of Hematology, Department of Medicine, Wayne State University College of Medicine, Detroit, Michigan.*

A comprehensive reference volume drawing together an enormous amount of data on trace element research. It is now possible to measure accurately the amounts of many elements present in living tissues, and the importance of such elements as chromium, copper, manganese, selenium, and zinc in human metabolism is becoming more and more apparent. The book describes the biochemistry and metabolism of each element and the effects of deficiency and excess.

Toxic elements such as cadmium, lead, and mercury, are also covered. (*Series: Topics in Hematology*)

Angels and devils of science

R. H. Pritchard

Recombinant DNA: The Untold Story. By J. Lear. Pp. 280. (Crown: New York, 1978.) \$8.95.

THIS book contains a brief account of the discoveries and discoverers that made DNA splicing exploitable as a method of amplifying genes and creating new hybrids. It also contains a blow by blow account of the rise and fall of the conviction, and the public debate it led to, that the synthesis of hybrids from organisms whose DNAs do not naturally encounter one another is hazardous because it could lead inadvertently to the creation of new pathogens not controllable by established methods.

This hypothesis in its general form was always a highly speculative one unsupported by any evidence. Its validity was determined not by reasoned argument but by shows of hands at mass meetings and *ex cathedra* pronouncements from groups of eminent scientists. The scientific community was led into a headlong rush to impose upon itself the most stringent safety precautions against totally hypothetical hazards. It caused intelligent scientists to engage in acts of public self-immolation and to public announcements of the destruction of valuable but completely harmless strains of microorganisms. Later there was cheating to get around the regulations and sneaking to get round the cheaters. It has cost millions of dollars and millions in other currencies so far to finance containment laboratories and containment bureaucracies. It has been a damaging episode in the relationship between the scientific community and the public, and there must be important lessons to be learned from it. Readers of Lear's book are in danger of learning the wrong lesson. He is not a dispassionate reporter. He has a particular point of view which leads him to a particular interpretation of the events he records. On the other hand, he has researched his material to a considerable depth. His account of events rings true. He writes entertainingly and often draws amusing and recognisable pen portraits of the central characters. His account of the science itself is admirably lucid with few howlers. It is a book well worth reading.

John Lear doesn't question the validity of the Frankenstein-monster hypothesis. Thus the story he tells is a story of the triumph of good over evil, with the devil threatening a comeback towards the end and the final outcome even now undecided. Good is accountability of scientists to society. The devil, on the other hand, believes in unbridled licence for anyone to do whatever experiment he chooses, accountable to no-one but himself. It is a fairy story, of course, but it seems to be one that Lear believes in.

According to Lear a telephone call from one Robert Pollack to a Professor Berg in 1971 sparked off the great debate. Pollack was worried that Berg proposed to propagate the genome of the monkey virus SV40 in *Escherichia coli* by splicing it into a bacterial virus called λ . Berg subsequently abandoned the experiment. Both men later organised a conference on Biohazards in Biological Research which seems to have been devoted primarily to the hazards of handling tumour virus. The conference did not get widespread publicity inside or outside the scientific community. Lear argues that it was because the press was not alerted. Later in discussing events which really did start the ball rolling he argues that the Pollack-Berg message needed time to sink in. There is another possibility. Pollack's concern was based on a reasoned (although not necessarily valid) extrapolation from well-founded observations. SV40 produces tumours in some animals and causes transformation of human cell lines to forms with cancer-like properties. It also forms natural hybrids with adenoviruses which cause respiratory infections. Anyone familiar with these facts, with the frequency with which animal viruses form hybrids naturally, and with the uncertainty surrounding their pathogenicity, would not lightly synthesise large quantities of SV40 DNA in *E. coli* and it would not be unnatural for a virologist to express his worries to a biochemist whose background might not have alerted him to the potential hazards. But these commendable initiatives could not possibly engender an impassioned debate between the angels and devils of the scientific world. Who would act the devil? Scientists are no more mis-

chievous, no less intelligent and no more suicidal than the population at large.

A conference two years later provided a more favourable breeding ground for devils. A new and trivially simple method of gene splicing was announced. Anybody could do it. The particular and rational concern (about the lack of care in handling the DNA of suspected pathogens like animal viruses) began to merge with a general and irrational one (that any new combination of genetic material will produce organisms with unknown, unpredictable, and hence potentially hazardous properties).

Devils would soon point out that to be a hazard to the population at large the novel hybrid would not only need to be pathogenic but have a positive adaptive value. To them the probability that, for example, a random insertion of fruitfly genes into *E. coli* could produce such an organism seemed, to put it simply, rather less than the probability that a random splicing of bits of the computer tape of an automatic knitting machine programmed to produce pullovers into the tape of a machine programmed to produce socks would not only lead to the generation of a wearable garment (the pullox) but one which would capture a significant share of the market. Naive angels (who seemed to believe that a cholera epidemic could be caused by *E. coli* containing a cholera toxin gene, that diarrhoea could be caused by *E. coli* carrying a cellulase gene, and tooth decay by *E. coli* with a tooth decay gene kit from *Streptococcus mutans*) thought the probability was too high to be ignored. Smart angels agreed that the probability was negligible but asserted that it could not be claimed to be zero. And if it wasn't zero, to ignore it proved one to be a devil. Lovable angels argued that a little nonsense was a small price to pay for a safe code of practice for animal viruses. There were also naive lovable angels who were properly concerned about the spread of plasmid-borne drug resistance in bacteria. They wanted to ban the synthesis of bugs resistant to new combinations of antibiotics by gene splicing. When devils pointed out that to solve a problem the first step was to properly diagnose it, naive lovable

angels comforted themselves with the thought that a ban could do no harm, and it might even help just a bit.

Such a confusion of issues, such a mixture of motives, plus a widespread lack of awareness of population biology and ecology among the protagonists, were necessary raw materials for a controversy. But to raise the emotional temperature and politicise the issue required another factor. Pollack's spark needed a torch and it has been suggested to me by many people that the torch was the deep concern amounting to guilt of many United States scientists with the misuse of scientific knowledge—a concern that was born out of Los Alamos and came to a head for biologists when defoliants were used in an unpopular war. Lear's book offers support for this view at many points and a Roy Curtiss III, who emerges as its hero, is a good exemplar of this factor. He circulates one thousand copies of a sixteen-page signed testimony of self-criticism, admitting his innocent guilt and the frightening consequences of his work, pledging himself to be good in the future, and demanding much more severe constraints than were being mooted at the time. His stature in Lear's eyes is further enhanced by the revelation that he went to the library some years later and discovered that his work wasn't as frightening as he had thought. Thus he not only earns his role as a repository of the conscience of the scientific community but demonstrates his honesty and humility as well.

The bandwagon of public accountability came to a euphoric climax at Asilomar. A panel of assorted angels had been working hard on a code of practice which was accepted, after being modified a bit, because no one else had a better one. For the first time the scale of the hazards of genetic engineering were divined and graded and the revelations confirmed by a show of hands (allowing lesser mortals to publicly affirm their concern). For the first time the public could see that scientists believed that the theoretical hazards were more dangerous than real ones like, say, cholera or typhoid fever.

Before Asilomar public displays of concern could be indulged in at no cost. After Asilomar the bill was presented in the form of a blanket of controls out of all proportion to any reasonable assessment of hazards. Scientists handling totally harmless organisms found themselves embraced by a code of practice which assumed that they were dangerous pathogens. With minds thus concentrated there was growing pressure against the enshrinement of the code in legislation. Some people just went ahead and

ignored it. To Lear this lobbying and cheating proves his thesis that there are enemies of the people who will use any means fair or foul in the pursuit of unbridled scientific licence even to the point of danger to others. He has found his devils and in his enthusiasm to expose them his objectivity fails him. He even discovers a convention among scientists, which is flouted by his devils of course, but also by himself when it suits his purpose. This is the convention, new to me, that it is improper to cite unpublished work.

I should like to be able to record that those scientists who were collectively most influential in setting in motion the so-called debate on the hazards of genetic manipulation had, after due reflection, collectively used their influence to counterbalance the effect of their earlier statements. They have not done so and consequently Lear's thesis is bound to retain some credibility.

This book occasionally alludes to events abroad. The British Parliament reacted with alacrity to the 1974 petition and the Working Party it established completed its work with similar speed. We get a pat on the back for this but I fear that what it

demonstrates is the action of reflexes trained not to be caught with pants down in an unusually conservative society. Unfortunately, the same reflexes make any relaxation of the code of practice here much more difficult than in the more open and adventurous United States. Not yet for us the return to reason represented by the recent statement of the Director of the US National Institutes of Health that the burden of proof is shifting towards those who would restrict recombinant DNA research.

This episode should help to educate the public about science and scientists. The realisation that eminence does not necessarily equal wisdom, that expertise in one area can equal ignorance in another, that scientists are no more objective than anyone else, is healthy enough. The conclusion I draw from this is that on matters of policy we should base our decisions on the quality of arguments and not upon the status of those who expound them, as we have learned to do outside science. If this precept had been followed, Lear would have no story to tell. □

R. H. Pritchard is Professor and Head of the Department of Genetics at the University of Leicester, UK.

Enigmas of filterable, invisible entities

David Baltimore

An Introduction to the History of Virology. By A. P. Waterson and Lise Wilkinson. Pp. 237. (Cambridge University Press: Cambridge and London, UK, 1978.) £12.

TODAY virology is a well defined discipline: it is the study of infective, intracellular parasites that lack the capability to synthesise their own proteins. This definition distinguishes viruses from other microbes and encompasses entities with sufficient similarities to provide the unity needed for defining a field of biology. But even up to the 1930s the essential nature of viruses was so obscure that the basic unity of their life-style was not apparent. All that was known about viruses before the advent of molecular biology was that they were small enough to pass through filters that trapped bacteria, they were invisible in the light microscope and they would not grow in the absence of living cells. And, of course, they caused a range of nasty diseases in humans,

other animals and plants; finding out more about them was therefore imperative.

The bacterial viruses, a group of viruses that were generally thought to be curiosities, generated the clues that brought the modern understanding of viruses. They provided the research materials from which much of molecular biology developed; and once the nature of genes and how they function was known, viruses became understandable creatures. The history of virology is thus a history of ideas as well as a history of discoveries. At first the recognition that certain diseases were caused by tiny, intracellular parasites was a triumph but the later realisation that these agents share the property of being stripped down to the bare essentials of replication was needed to provide a conceptual unity to virology.

There are so many viruses and the road to their understanding has been so complex that to write a history of virology would be an enormous undertaking. Waterson and Wilkinson were right to start with *An Introduction to the History of Virology*, in which they could define the outlines of the history. They did this with a strong emphasis on the conceptual problems.

The early part of their short book takes us back to late nineteenth century when Ivanovski and Beijerinck independently realised that what we now call tobacco

Photosynthetic Carbon Assimilation

edited by **Harold W. Siegelman**
and **Geoffrey Hind**

Brookhaven National Laboratory, Upton, New York

Covering the broad spectrum of current research directed at the enzyme ribulose 1,5-bisphosphate (RuBP) carboxylase, this volume consolidates the most significant research literature, bringing together information from such diverse fields as agronomy, plant physiology, biochemistry, and crystallography. *Basic Life Sciences, Volume 11*. 456 pp., 1979, \$42.50 (\$51.00/£26.78 outside US)

Beyond the Green Revolution The Ecology and Politics of Global Agricultural Development

by **Kenneth A. Dahlberg**

Western Michigan University

Assesses the past, present, and future use of agricultural technology in under-developed areas, emphasizing the adaptation of western agricultural policies, and the connection between society and environment. 270 pp., illus., 1979, \$17.95 (\$21.54/£11.31 outside US)

Chemical Mutagens Principles and Methods for Their Detection Volume 5

edited by **Alexander Hollaender**

Associated Universities, Inc., Washington, D.C.

and **Frederick J. de Serres**

National Institute of Environmental Health Sciences

"... chapters are authoritative and these ... volumes now stand as the best concentrated source of information on chemical mutagens and mutagen testing."

—**Sheldon Wolff**, *Radiation Botany*

The fifth volume of this acclaimed treatise examines such topics as body fluids for detection of mutagenic agents, yeast as an assay system for industrial mutagens, and specific-locus mutations. 364 pp., illus., 1978, \$29.50 (\$35.40/£18.59 outside US)

Genetic Mosaics and Chimeras in Mammals

edited by **Liane B. Russell**

Oak Ridge National Laboratory, Oak Ridge, Tennessee

In this profusely illustrated volume, active investigators report on current mosaic and chimera research involving both humans and rodents. Organized by broadly conceived problem areas, specific topics covered include the use of chimeras to study developmental potency and mathematical analysis of mosaic patterns. *Basic Life Sciences, Volume 12*. 500 pp., 1978, \$39.50 (\$47.40/£24.89 outside US)

Genetic Engineering Principles and Methods Volume 1

edited by **Jane K. Setlow**

Brookhaven National Laboratory, Upton, New York

and **Alexander Hollaender**

Associated Universities, Inc., Washington, D.C.

The first volume in a new series presents papers by internationally known researchers concerning the application of recombinant molecule technology to structural studies of the genomes of higher plants and animals, and discussions of future research possibilities. 278 pp., illus., 1979, \$29.50 (\$35.40/£18.59 outside US)

Environmental Pollutants Detection and Measurement

edited by **Taft Y. Toribara, James R. Coleman,**
Barton E. Dahneke, and Isaac Feldman

University of Rochester

This book includes descriptions of measurement techniques utilizing electrothermal atomization, atomic absorption, lasers, spectroscopy, photometry, electron microscopy, microprobe analysis, gas permeation, X-rays, and neutron-activation analysis. *Environmental Science Research, Volume 13*. 512 pp., 1978, \$42.50 (\$51.00/£26.78 outside US)

Pentachlorophenol Chemistry, Pharmacology, and Environmental Toxicology

edited by **K. Ranga Rao**

University of West Florida

Internationally recognized scientists review the latest investigations regarding pentachlorophenol (PCP) and related chlorophenols, including their impact on the environment, and their pharmacological and toxicological qualities. *Environmental Science Research, Volume 12*. 416 pp., illus., 1978, \$37.50 (\$45.00/£23.63 outside US)

The Geomagnetic Field and Life Geomagnetobiology

by **A. P. Dubrov**

Academy of Sciences of the USSR

translated from Russian by **Frank L. Sinclair**

translation edited by **Frank A. Brown, Jr.**

This treatise, written by a noted Soviet biophysicist, represents the first general review of the biological effects of the geomagnetic field. The author emphasizes the decisive role of the geomagnetic field in all phenomena occurring in the biosphere. 336 pp., illus., 1978, \$25.00 (\$30.00/£15.75 outside US)

The Respiratory Functions of Blood

by **Lars Garby and Jerry Meldon**

University of Odense, Denmark

"... a remarkable book that occupies a unique place in setting forth our present knowledge of blood as a medium for the transport and exchange of oxygen and CO₂. ... a valuable book for workers concerned with blood and respiration, both in the research laboratory and in clinics where there is a strong orientation toward research. There is no other book comparable to it..."

—**John T. Edsall**, *Professor Emeritus,*
Harvard University

A volume in the *Topics in Hematology* series—series editor: Maxwell M. Wintrobe. 300 pp., illus., 1977, \$21.50 (\$25.80/£13.55 outside US)

Addison-Wesley Advanced Book Program

BIOPHYSICAL and PHYSIOLOGICAL SYSTEMS ANALYSIS Based on Lectures to Graduate Students

Erol Başar, Hacettepe University

An excellent, concise text presenting applications of the very powerful systems approach to biological, physiological phenomena and signal analysis problems in the clinic—problems include autoregulatory mechanisms in the circulatory system, smooth muscle dynamics, and the generation and transmission of electrical signals in the brain, general problems of rhythmicity in biology. The book appeals to graduate students and research scientists in biophysics and physiology, biomedical engineering, EEG and neurophysiology, systems engineering, theoretical biology, as well as biostatisticians and physiological psychologists.

"The book should provide interesting and stimulating reading for engineers with an interest in the problems of medicine and biology and will be useful to biologists and biophysicists in explaining and illustrating the application of the very powerful systems approach to biological and medical problems."

Journal of Medical Engineering and Technology

"This book can be highly recommended. The concepts and objectives are clearly indicated at each stage and summarized intelligently. The reader may even be stimulated to search further into the intricate transformations of signal coding that are presumably the basis of all behavioural reactions."

Biomedical Education

Contents INTRODUCTION, DEFINITIONS AND CONCEPTS, BIOLOGICAL SYSTEMS ANALYSIS PROGRAM, THE CIRCULATORY AUTOREGULATION, SMOOTH MUSCLE CONTRACTIONS, NONLINEARITIES IN BIOLOGY, ELECTRICAL SIGNALS FROM THE BRAIN, AN OVERVIEW, AUTHOR and SUBJECT INDEXES. (References at end of each chapter).

BIOCHEMICAL SYSTEMS ANALYSIS A Study of Function and Design in Molecular Biology

Michael A. Savageau, University of Michigan

Foreword by Robert Rosen, Dalhousie University

"This book is an excellent text covering the mathematical analysis of control of biochemical reaction networks involved in metabolism and gene expression. Although the book is mathematically oriented, experimental observations on which the analyses are based are carefully discussed and explicitly referenced."

American Society for Microbiology News

"For the first time the subject has been tackled in a single comprehensive text. It is a superb book which challenges any university teacher of biochemistry to consider teaching the more integrative aspects of the subject. Savageau's book is scholarly, coherently planned, and extremely well written. Its publication is to be welcomed as a major contribution to the literature of modern biology."

Biologist/Journal of Biological Education, (London)

Contents CHARACTERIZATION OF MOLECULAR MECHANISMS: Introduction.

Mathematical Descriptions of Chemical Change. Enzyme-Catalyzed Reactions. Modification of Enzyme Activity. INTEGRATION AND SYSTEMS ANALYSIS: General Nature of Biochemical Systems. Linear Systems Analysis. Nonlinear Systems Analysis. Dynamic Solutions by Computer.

BIOCHEMICAL AND GENETIC APPLICATIONS: Simple Feedback Inhibition. Optimal Properties of End-Product Inhibition. Dynamic Properties of End-Product Inhibition. Feedback Inhibition in Branched Pathways. Cascaded Enzymatic Mechanisms. Mechanisms of Gene Action. Genetic Regulation: Inducible Systems. Genetic Regulation: Repressible Systems. Appendices. Author and Subject Indexes.

THE GENERAL POINT PROCESS

Applications to Structural Fatigue, Bioscience, and Medical Research

V.K. Murthy, UCLA and University of Southern California

APPLIED MATHEMATICS AND COMPUTATION SERIES

Robert Kalaba, Series Editor

"A theory involving the distribution of events or points in any given time frame (i.e., the general point process) is developed, and several fields of application of the theory are considered. 'Events' are understood to mean such occurrences as a pedestrian being knocked down by a car or a person suffering an acute myocardial infarction. Estimation statistics, the cumulative point process, the multi-dimensional point process, applications to the theory of cumulative fatigue damage of structures, the superposition of arbitrary point processes, applications of the theory of the general point process to life test data, and applications to biological and medical problems are discussed."

International Aerospace Abstracts

Contents PRELIMINARIES, ESTIMATION, THE CUMULATIVE POINT PROCESS, THE MULTIDIMENSIONAL POINT PROCESS, ESTIMATION OF THE VARIANCE OF THE COUNTS RESULTING FROM A TWO-DIMENSIONAL PROCESS, APPLICATIONS TO THE THEORY OF CUMULATIVE FATIGUE DAMAGE OF STRUCTURES, THE SUPERPOSITION OF ARBITRARY POINT PROCESSES, APPLICATIONS OF THE THEORY OF THE GENERAL POINT PROCESS TO LIFE TEST DATA, APPROPRIATE DISTRIBUTIONS FOR THE INTER-EVENT INTERVALS FOR THE POINT DAMAGE PROCESSES AND THEIR ESTIMATION PROBLEMS, A SIMPLE TWO-PARAMETER WEIBULL MODEL FOR THE INTER-EVENT DISTRIBUTION, APPLICATIONS TO BIOLOGICAL AND MEDICAL PROBLEMS, FURTHER APPLICATIONS TO BIOLOGICAL AND MEDICAL PROBLEMS, BIBLIOGRAPHY.

mosaic virus was so very much smaller than a bacterium that it ought to be considered a separate form of life. One must stand in awe of the pioneers of virology who, working with crude filters and imprecise assays, were able to bring to light a new aspect of the living world. In Beijerinck's earliest publications he originated the modern concept of a virus; the remarkable insight implied by his ability to make such a conceptual leap stands as one of the great intellectual achievements of biology. But, living up to their title, the authors only give us a passing taste of Beijerinck's work. Even a brief discussion of the origins of virology should tell us more about how Beijerinck derived his conclusions.

Another recent short book, Sally Smith Hughes' *The Virus: A History of the Concept* (Heinemann: London, 1977) provides a deeper look at Beijerinck's work. Hughes points to a remarkably simple experiment as the source of Beijerinck's concepts; he put infected plant sap on an agar surface and showed that the infective principle would diffuse through the agar. From this experiment he concluded that the virus is "dissolved and not corpuscular" leading to his concept of tobacco mosaic disease as a "contagium vivum fluidum". Beijerinck saw viruses in chemical terms, possibly as a partial result of his friendship with van't Hoff. This may have been the genesis of his pronouncement in 1898 that:

"... it is to some extent an explanation to consider that the contagium in order to reproduce itself must be incorporated into the living protoplasm of the cell into whose multiplication it is so to speak passively included."

After describing how Loeffler and Frosch opened animal virology with their discovery of the agent of foot and mouth disease virus, Waterson and Wilkinson take us through the discovery of a number of other animal viruses. They follow with discussions of vaccines and tissue culture. They emphasise the difficulty of understanding the nature of viruses without an appreciation of the molecular events underlying genetic phenomena and they show how bacterial viruses provided crucial experimental material for the development of molecular biology. In turn, they show how the development of molecular biology led to an understanding of the nature of viruses. After chapters on plant and insect viruses and on "eruptive fevers" they turn to tumour viruses, a subject that cries out for a more extensive history documenting the shifts of belief about the role of viruses in experimental and human cancer.

For someone like me, who entered virology in 1960 when the essential nature of viruses as intracellular parasites was commonly accepted, it is fascinating to see how the early virologists wrestled

with the enigmas of filterable, invisible entities that would not grow in the absence of living cells. Although this book is often a sketchy introduction and sometimes becomes a catalogue of events, it is a very valuable probe into a central aspect of the history of biology and medicine. Among its useful aspects is a collection of short biographies of

many of the important contributors to unravelling the puzzles presented by viral diseases. It also contains a list of general references and a useful bibliography of the original early literature. □

David Baltimore is an American Cancer Society Professor of Microbiology at the Massachusetts Institute of Technology, Cambridge, Massachusetts.

Plant hormones

Phytohormones and Related Compounds: A Comprehensive Treatise. Vol 1: The Biochemistry of Phytohormones and Related Compounds. Edited by D. S. Letham, P. B. Goodwin and T. J. V. Higgins. Pp.641. (Elsevier/North-Holland/Biomedical: Amsterdam, Oxford and New York, 1978.) \$99.50; Dfl.224.

To be invited to review a book of this nature is a mixed blessing. It is, of course, a privilege to own a copy of the book; on the other hand, wading through 640 worthy but inexpressibly turgid pages in order to pronounce on its value to a prospective reader would be a thoroughly dismal task. I have not, therefore, read this book; I have sampled it. As it is questionable that books like this are ever meant to be read, then my approach is probably representative of any likely customer.

The book is sub-titled *A Comprehensive Treatise*, and this first volume undoubtedly lives up to that claim, although it does seem to be rather out of date. In a survey of the substantial reference lists given at the end of each chapter, I only encountered a handful of 1977 references, and these were principally those of the authors. Even 1976 seemed to be a rather rare date, suggesting that most of the preparation of the book was completed in mid-1976, with perhaps some special references added at the proof stage. Consequently, those looking for up-to-date reviews would be better advised to use *Annual Reviews*, or one of the other periodicals. As a solid compilation of the factual information relating to plant hormones, on the other hand, this book can have no equal.

The first chapter—which I did read—is a thought-provoking, partly historical, account of some of the more provocative general questions concerning plant hormones and their study. It is the only part of the book in which the conceptual content matches the factual content, and is thereby especially welcome. The density of fact, and its repetitive corroboration, is so high in the rest of the book as to make it difficult to digest. Apart from the first

chapter, one would be unlikely to open this book unless one had a specific technical point in mind. On the other hand, it would be invaluable for that purpose.

This first part of the treatise covers the biochemistry of hormones, and does so in the traditional manner, by considering each group of hormones separately. Chapters 2–6 cover auxins, gibberellins, cytokinins, ethylene and abscisic acid in a more or less uniform format, dealing with isolation, identification, chemistry, assays, structure-activity relationships, biosynthesis, metabolism, transport, and the effects of various stimuli on hormone levels. These chapters seem to me to be excellent contributions, and it is extremely valuable to have all this information in one source. Following these chapters is an extremely useful compilation of data on naturally occurring plant growth regulators other than the principal hormones.

The remaining chapters (over 200 pages) are concerned with the effects of hormones on cell structure and metabolism in general, and on DNA replication, transcription, translation, and on post-translational control points. I found the chapter on ultrastructural effects of the hormones particularly rewarding, as it emphasises the syndromic nature of hormone action in higher plants, and illustrates the naivety of assuming that cell-free studies will tell all. These chapters are all written by Drs T. J. V. Higgins and J. V. Jacobsen and represent a considerable, and as far as I could tell, highly critical *tour-de-force*.

My impression, therefore, is of an excellent, though very viscous, treatise which should find a place on every plant physiologist's shelf. My absolute certainty that it will not do so, however, comes from the horrendous price. At \$99.50, or £50, this book—remember it is yet only half a book—will not only be out of the reach of individual purchasers, it will also be expensive for most college or university libraries. What purpose can be in putting together a book which will only be available to a select few?

H.

H. Smith is Professor of Botany, University of Leicester, UK.

Biological effects of ultraviolet radiation

UV-A: Biological Effects of Ultraviolet Radiation, with Emphasis on Human Responses to Longwave Ultraviolet. By J. A. Parrish, R. A. Anderson, F. Urbach and D. Pitts. Pp.262. (Plenum: New York and London, 1978.) £15.75.

It has long been known that sunlight has both beneficial and deleterious effects on man. Many of these effects are caused by the ultraviolet region of the solar spectrum, which has somewhat arbitrarily been divided into three sections—UV-C (wavelength 200–290 nm), UV-B (290–320 nm) and UV-A (320–400 nm). The biological responses of cells, of skin and of the eye to UV-C and UV-B have been well studied. On the other hand relatively little is known about the responses to UV-A, because on a dose-for-dose basis it is much less potent than the lower wavelength regions of the spectrum. The authors of *UV-A* stress that it is nevertheless of growing importance to assess the biological effects of UV-A.

Although it is of relatively low potency, the incidence of UV-A reaching the Earth from the Sun is very much higher than that of UV-B and UV-C. Also, UV-A is finding increasing use both in industry and in medicine, in the latter case particularly in conjunction with photosensitising drugs. Three problems in studying responses to UV-A crop up in almost every chapter: the inadequate dosimetry in most cases; the difficulty in obtaining sources of sufficiently high intensity; and the possibility that the effects observed may in fact be due to contamination of the UV-A with trace amounts of the much more potent UV-B. The authors have therefore wisely not confined themselves solely to UV-A but in each chapter they have discussed effects of ultraviolet radiation of different wavelengths and used this as a background against which to consider the (usually rather scanty) work with UV-A.

The book is very comprehensive in the range of subjects covered, commencing with light sources, filters and detectors, and proceeding with optical properties of the eye and skin—the parts of the body most affected by ultraviolet light. There follow chapters on the biological effects of ultraviolet light at various levels, starting with molecular studies on cells, and continuing with effects on the skin (erythema, tanning, skin ageing and skin cancer) and the eye (keratitis and cataracts).

chapter on the uses of UV-A involving human exposure, and one on safety and protection. The former is chiefly concerned with photochemotherapy using psoralens and UV-A (PUVA) for the treatment of various skin ailments such as psoriasis and vitiligo. PUVA treatment is one of the few instances in which it is quite certain that the biological response is indeed mediated by UV-A rather than by shorter wavelength light. A balanced account is presented of the undoubted benefits of this therapeutic regime and the risk against which this must be offset, namely that in the long term the therapy itself may induce skin cancer.

A most impressive feature of this book is the way in which each topic is introduced with a succinct and lucid description of the system under study, so that the non-specialist reader is provided with the necessary basic information to understand what is subsequently discussed. This applies to

aspects of physics (for example, excited states), biochemistry (DNA repair), physiology (structure of the skin and eye) and medicine (description of psoriasis). The authors have therefore been remarkably successful in producing a book which should be comprehensible to anyone interested in the subject matter, whether he be physicist, biologist or clinician. As so little seems to be really known about the biological effects of UV-A at present, it is questionable whether the subject merits a whole book. On the other hand it contains much useful information on related topics. It will therefore be a handy reference book for any photobiologist and it should certainly be compulsory reading for anyone working with UV-A.

Experimental phycology

Physiological and Biochemical Methods. Handbook of Phycological Methods. Edited by J. A. Hellebust and J. S. Craigie. Pp. 512. (Cambridge University Press: London, New York and Melbourne, 1978.) £18.

ALGAE serve as experimental tools for physiologists, biochemists, molecular biologists, organic chemists and so on, but the experimental techniques which these workers use are scattered throughout the literature. In 1967 the Phycological Society of America had the good sense to promote the publication of a source book on methods used in experimental phycology, written by phycologists. This one book never appeared; instead four were eventually commissioned, and although progress in getting these off the ground was slow initially (the first, on culture methods and growth measurements, appeared in 1973), the second, on physiological and biochemical methods, has been worth waiting for.

This is a "how to do it" book which should find a place on the shelves of any experimental phycologist. Not that I think it will remain on the shelves for long—it will be in constant use by graduate students, teachers, and others interested in algae. Its great advantage is that within the one cover there is such a mine of information. There are 46 chapters, by 46 authors (not necessarily one each), arranged in

seven major sections: isolation of organelles and membranes (how to isolate chloroplasts, microbodies, membranes, and so on); analysis of chemical constituents (pigments, protein, glycerolipids and fatty acids, β -1,3 glucans, alginic acid, ATP, and so on); enzyme assays (nitrate reductase, ribulose 1,5-bisphosphate carboxylase, aldolases, and so on); measurement of physiological and biochemical processes (uptake of organic substrates, photosynthetic rates, nitrogenase activity, protein synthesis, and so on); nutrient uptake (nitrate, phosphate, and so on); ion content and transport; and use of inhibitors (a most useful chapter).

Each methods chapter is factual, with the sources of algal material (most workers on micro-algae still seem to use strains of *Chlamydomonas*, *Chlorella* or *Euglena*), equipment and chemicals (sometimes even the catalogue numbers) clearly given. There is usually a short discussion and some key references (few later than 1975). There is a useful appendix to the book which lists the addresses of many chemical and equipment suppliers and the suppliers of algal cultures (a notable exception is the American Type Culture Collection of Bacteria, where the blue-green algae are classified as cyanobacteria!)

A possible problem with such a book is trying to ensure that most of the important techniques are included and yet the price is not exorbitant. The book has most of the important ones but there are surprising omissions. One example: the key NH_4^+ -assimilating enzymes, glutamine synthetase and glutamic acid dehydrogenase, are not

New books from CAMBRIDGE

Mechanisms of Drug Action on the Nervous System

R. W. RYALL

Drugs affecting the peripheral nervous system and the brain are among the most widely used in contemporary medicine. This book analyses currently available information on the therapeutic or toxic effects of drugs in relation to the underlying physiological processes and pathological phenomena. It attempts to fill the gap between the many excellent textbooks of therapeutics and the highly specialised research reviews and monographs. The book is aimed principally at undergraduate students in the natural and medical sciences.

Paperback £6.95 net

The Journal of Experimental Biology

Editor J. E. TREHERNE

An annual review volume is being produced based on the proceedings of a workshop meeting. The topic of the first of these, published later this year, is *Cellular Oscillators* and it is organised by Michael Berridge and Paul Rapp.

The review volume will be supplied to subscribers of the Journal in 1979 and will also be available for separate sale.

Volumes 78 - 83 are being published in 1979.
Subscription: £10.00 per volume,
£50.00 per year

Cell-Cell Recognition

Edited by A. S. G. CURTIS

Cell-Cell recognition phenomena occur throughout all forms of life. Cells reject and select their own or closely related types in embryogenesis, regeneration and various immune processes. In this book particular attention has been given to a number of areas of current research. Most of the contributors to this volume have approached the subject by discussing the cell surface where cell-cell recognition phenomena usually take place.

The Invertebrates

R. McNEILL ALEXANDER

In this book, Professor McNeill Alexander, a highly distinguished zoologist, pursues a quantitative approach to the study of zoology, with particular emphasis on the experimental study of invertebrate structure and functioning. The book begins with an introduction to the most important modern zoological techniques and the principles of animal classification. This is followed by separate chapters devoted to the individual invertebrate phyla and to the experiments that have contributed to our understanding of them. Designed as a text for undergraduate courses in invertebrate zoology, this book conveys much of the flavour and interest of modern zoology.

ELECTRON MICROSCOPY IN HUMAN MEDICINE

Edited by **JAN VINCENTS JOHANNESSEN, M.D.**, Consultant Pathologist and Head of the Laboratory of Ultrastructural and Experimental Pathology, Norwegian Radium Hospital; and **Norsk Hydro's Institute for Cancer Research**

This wide-ranging but intensive reference series is a convenient aid for education, routine lab work, and research in histopathology, virology, microbiology, and other clinical specialties. By demonstrating the ultra-structural aspects of disease, it will help to stimulate the search for new diagnostic and therapeutic methods.

■ **VOLUME 1: INSTRUMENTATION TECHNIQUES** Transmission and scanning electron microscopy, fixation, embedding, staining, special stains for semithin sections, negative staining, cryo-sectioning, freeze-etching, electron probe X-ray analysis, stereology, histochemistry, autoradiography, paraffin, photography, the electron microscope, and occupational hazards. (0-07-032501-4) 1978, 348 pages, \$56.00

■ **VOLUME 2: CELLULAR PATHOBIOLOGY, METABOLIC AND STORAGE DISEASES** Cell and tissue structure and function, injury reactions, lysosomal disorders. (0-07-032502-2) 1978, 256 pages, \$34.50

■ **VOLUME 3: INFECTIOUS AGENTS** Viruses, bacteriophages, mycoplasma agents, bacteria, protozoa, and fungi. (0-07-032503-0) May 1979, 276 pages, \$45.00

■ **VOLUME 4: SOFT TISSUES, BONES AND JOINTS** Degenerative and inflammatory disorders, tumors, tumor-like conditions, soft tissue tumors, striated muscles. (0-07-032504-9) May 1979, 275 pages, \$45.00

■ **VOLUME 5: CARDIOVASCULAR SYSTEM, LYMPHORETICULAR AND HEMATOPOIETIC SYSTEM, RESPIRATORY TRACT** Heart, blood and lymph vessels, thymus, bone marrow, blood, lymph nodes, and spleen. (0-07-032505-7) July 1979, 274 pages, \$45.00

■ **VOLUME 6: NERVOUS SYSTEM SENSORY ORGANS, SKELETAL MUSCLE** Metabolic and demyelinating conditions, viral diseases and tumors of central nervous system, peripheral nerves, eye, inner ear, and respiratory tract. (0-07-032506-5) August 1979, 278 pages, \$45.00

■ **VOLUME 7: DIGESTIVE SYSTEM** Oral cavity, salivary glands, gastrointestinal tract, and exocrine pancreas. (0-07-032507-3) July 1979, 272 pages, \$45.00

■ **VOLUME 8: THE LIVER, THE GALLBLADDER, AND BILIARY DUCTS** Normal and pathological ultra-structure of liver parenchyma and biliary tract. (0-07-032499-9) April 1979, 224 pages, \$48.00

■ **VOLUME 9: UROGENITAL SYSTEM, PLACENTA, AND BREAST** Kidney, lower urinary tract, male genitalia, spermatozoa, female genital tract, placenta, ovary, and mammary gland. (0-07-032508-1) June 1979, 396 pages, \$54.00

■ **VOLUME 10: ENDOCRINE ORGANS, SKIN** Pituitary, thyroid, parathyroids, adrenals, and endocrine pancreas. (0-07-032509-X) October 1979, 280 pages, \$45.00

■ **VOLUME 11: SPECIAL APPLICATIONS AND FUTURE TRENDS** Advanced techniques such as fixation procedures, scanning electron microscopy, stereology, electron microscopy of molecules, and forensic medicine as well as some views on the future role of electron microscopy in human medicine. (0-07-032510-3) October 1979, 268 pages, \$45.00

To order all eleven volumes, place your order for the entire set (0-07-079276-3: \$494.00). Single volumes will be shipped individually to you as they are published.

SPECIAL ANNOUNCEMENT OF A NEW QUARTERLY

The new *Journal of Ultrastructural Pathology* is scheduled to begin publication in late autumn of 1979. Focusing primarily on human pathology, this journal will publish articles on cell biology, case histories, reviews of new instrumentation and techniques and book reviews. For instructions on the submission of articles for possible publication, write to the editors: *Jan Vincents Johannessen*, Dept. of Pathology, Norwegian Radium Hospital, Oslo 3 Norway or *Victor E. Gould*, Dept. of Pathology, Rush Medical College, Chicago, Illinois 60612 U.S.A.

For subscription information, contact Suzanne E. Heyl, Hemisphere Pub. Co., 19 West 44th St., New York, N.Y. 10036 U.S.A.

Also Available from McGraw-Hill—

■ **LABELLED ANTIBODIES IN BIOLOGY AND MEDICINE** by **Aurel Feteanu**, U. of Bucharest. Details the apparatus, solutions, buffers, and techniques needed to obtain, isolate, and purify antibodies for labelling. Also describes methods using fluorochromes, radioactive isotopes, ferritine, and enzymes while explaining their medical applications. Includes 360 photos — over 200 in full color. (0-07-020643-0) 1978, 410 pages, \$39.50

■ **PRINCIPLES OF BIOCHEMISTRY, SIXTH EDITION** by **Abraham White**, Distinguished Scientist, Syntex Research and Stanford U. Sch. of Med.; **Philip Handler**, President, National Academy of Sciences and Prof., Duke U. Sch. of Med.; **Emil L. Smith**, Chairman of Dept. of Biological Chemistry, UCLA Sch. of Med.; **Robert L. Hill**, Chairman of Dept. of Biochemistry, Duke U. Sch. of Med.; and **I. Robert Lehman**, Chairman of Dept. of Biochemistry, Stanford U. Sch. of Med. Gives massive coverage of sweeping new discoveries made since 1972, and concentrates throughout on medical aspects with new data on blood composition, plasma, clotting, hemoglobin and leukocyte structure and function, insulin, genetics, electrolytes, and hormones. Includes five brand new chapters on prostaglandins, viruses, immunoglobulins, complement, and the role of the thymus. (0-07-069759-0) 1978, 1492 pages, \$35.00

■ **THE METABOLIC BASIS OF INHERITED DISEASE, FOURTH EDITION** Edited by **John B. Stanbury**, Director of Dept. of Nutrition and Food Technology, MIT; **James B. Wyngaarden**, Chairman of Dept. of Medicine, Duke U. Sch. of Med.; and **Donald S. Fredrickson**, Director of National Institutes of Health. For each of hundreds of disorders, gives full data on known physiology, pathology, biochemistry, genetics, metabolism, inheritance patterns, and therapies, thereby helping to trace clinical symptoms directly to altered metabolic pathways. Covers newly discovered disorders and variants of well-established syndromes, and presents thousands of valuable references to original research. (0-07-060725-7) 1978, 1755 pages, \$65.00

All prices quoted in U.S. dollars and subject to change without notice.

Principles of Biochemistry, 6/E and **The Metabolic Basis of Inherited Disease, 4/E** available from McGraw-Hill in U.S. only. All other titles available through your usual supplier, from your local McGraw-Hill representative or office, or from Lenore Stanoch/Room 3064-73, McGraw-Hill International Book Company, 1221 Avenue of the Americas, New York, N.Y. 10020, U.S.A.

considered, yet there is room for a chapter on threonine deaminase (an interesting chapter on a rather exotic enzyme). However, the overall balance is good with the more unusual features of algae as plants, for example, the production of alginic acid and fucoidan being adequately dealt with.

The only disappointing part of the book is the plates which are poor; the paper is also thin, but there

is a good stout cover and an adequate index. At £18 for over 500 pages packed with useful information I don't grudge a penny. I recommend it strongly to all with an interest in experimental phycology.

W. D. P. Stewart

W. D. P. Stewart is Professor and Head of the Department of Biological Sciences at the University of Dundee, UK.

Neurochemistry and behaviour

The Chemistry of Human Behaviour. By H. L. Meltzer. Pp. 261. (Nelson-Hall: Chicago, 1978.) \$17.95.

BELIEF in the chemical governance or in the chemical signatures of behaviour has some centuries of history but little current exposition in popular writing. This book, which attempts "a progress report for the informed layman" on "knowledge of brain chemistry and how this might relate to human behaviour" thus had a welcome objective, but neither the expressed objective nor the book's title should be taken literally. Their embodiment is a collection of specialist essays in neuroscience, with a preponderance of neurochemical studies in experimental animals.

The subjects covered are for the most part already well collated or reviewed elsewhere and the text bears only occasional evidence of orientation to the informed layman. Indeed some parts will puzzle the informed chemist: arbitrary variations in bond-length in structural formulae, and giving for glutamine the structure of asparagine. The book's merits lie in giving a largely correct account of several research themes of the past 10 or 20 years, in which chemical methods have been applied in understanding the structure or working of the brain and its influence on behaviour. These themes include malnutrition and brain development; inborn chemical abnormalities; the ion exchanges of nerve impulses; neurotransmitters; the actions of drugs including amphetamines, opiates, lysergic acid diethylamide, and steroid hormones; and chemical correlates of learning and of mental illness. The book's index and Figures are satisfactory, and it carries a 5-page list of books and reviews suggested for further reading. The penultimate chapter on ethical considerations is an excellent and timely exposition of the reasonable researcher's approach to experimentation with animals and human subjects. The chapters on flow of information and on the physical struc-

ture of the brain, though non-chemical, are also apposite.

A book designated to give informed laymen an appreciation of a developing technical subject presents its own specific problems which have been met only partially by Dr Meltzer. His writing in general is crisp, factual and without involved sentences. Some chapters, however, are constructed to attract attention to an extent which, by the chapter's end, is disappointed. Some carry an introductory paragraph only tenuously related to the chapter's main subject; others imply by their title more than current knowledge justifies. Thus "The Chemical Organisation of the Brain" might lead the reasonable layman to expect an exposition of how and why the numerous chemical structures described and illustrated are organised, or organise other components, to yield a brain rather than another organ of the body. Here he will be disappointed and will learn only on the last of the 20 pages involved, that "This has been a brief survey of chemical localisation in the brain . . . intended as an introduction to the diversity of chemical function. . . ."

The most successful expositions of technical knowledge of the brain for general readers have, recently, come from neurophysiology neuroanatomy or psychology. It is significant that the authors concerned with those expositions have not attempted to survey a large proportion of the current research in their subject: rather, they have chosen an intellectually intriguing theme central to their own interests and have been highly selective in the information presented to expound their viewpoints. Their pictures of the brain have included little if any neurochemistry at many points where neurochemistry would have been relevant. Comparably intriguing expositions from a neurochemical viewpoint have yet to be written: despite Dr Meltzer's book, the challenge remains open.

Capture-recapture for biologists

Michael Begon

By stressing the importance of biological context and the commonsense basis of the methods, this book aims to give biologists, at all levels, the confidence to use capture-recapture models for the assessment of animal population size, and to interpret the results they obtain sensibly.

The mathematical details of a variety of methods are treated in a clear and often novel way that requires little mathematical knowledge and there are useful sections on the actual techniques of capture and marking.

An Introduction to the Interpretation of Quantal Responses in Biology

P. S. Hewlett and R. L. Plackett

This guide to the interpretation of quantal (all-or-none) responses to such agents as pesticides or drugs covers both probit and logit analysis, although the latter — which is mathematically the simpler — is given prominence. The authors deal in a distinctive manner with the theory of responses to mixtures of drugs, and discuss certain topics rarely touched on in other books: namely, dose-response curves for heterogeneous populations, the theory of monitoring insect populations for resistance, time and response, and the general nature of quantal responses.

Investigating Chromosomes

Adrian F. Dyer

This book strikes a balance between the theoretical and the practical aspects of cytogenetics. Assuming little prior knowledge, the local theoretical exposition is matched at every stage by practical sections that allow the student to investigate or visualise each stage of chromosome activity as it is introduced. All the practical routines are variations on one basic technique and are applicable to a wide variety of plant and animal material.

Sedimentary environments

Sedimentary Environments and Facies. Edited by H. G. Reading. Pp. 557. (Blackwell Scientific: Oxford, UK, 1978.) Hardback £22.50; paperback £13.

THIS book describes modern sedimentary environments and their ancient analogues. For each major facies the editor has arranged for a chapter to be written by an internationally recognised authority on that particular topic. The book commences with an introductory chapter and a chapter on facies by the editor. These are followed by chapters on alluvial, lacustrine and desert deposits by Collinson. Elliott continues with chapters on deltas and clastic shorelines, and these are followed by a chapter by Till on arid shorelines and evaporites. Johnson has contributed a chapter on shallow siliclastic seas (*sic*) and this is followed by one from Sellwood on shallow-water carbonates.

Moving into deeper water Jenkyns and Rupke cover pelagic environments and deep clastic seas respectively. Edwards concludes the spectrum of environments with a contribution on glacial deposits. For a finale Reading and Mitchell have written a chapter relating facies to plate tectonics and the book closes with an epilogue from the editor, a bibliography and a subject index.

As the preceding resumé shows, this work is a veritable *tour de force*. It is well researched, well written and comprehensive, both in the range of environments described and in the global coverage of supporting case-histories. The illustrations all appear to have been redrawn from their original sources so that the book has a pleasing uniform appearance (though this review copy had several grey pages due to an apparent shortage of printers ink).

The emphasis of most of the authors is on the relationship between sedimentary processes and the macroscopic features of their deposits. Thus, the major theme of the book is concerned with the study of lithological sequences and their contained sedimentary structures and fossils.

The emphasis is on macrofacies rather than microfacies. It would have been interesting to have had contributions from this distinguished team of authors on the relationship between sedimentary processes, and the texture and petrophysics of their deposits. This would have widened the appeal of the book for many industrial geologists concerned with the relationship between facies, porosity and permeability.

sections on carbonates, which contain not a single microphotograph.

Similarly it would have been useful to read how the authors see facies analysis in relation to other branches of geology. One of the most stimulating chapters is the one which shows how facies relate to tectonics. It would be interesting to know more about the relationship of facies to stratigraphy (both conventional and seismic), to microfacies and petrophysics (as already mentioned), and to the ways in which facies analysis is applied in the exploration for coal, oil, gas, water and sedimentary ores. This deficiency is particularly apparent when subsurface case-histories are described. It is not sufficiently stressed that these have been interpreted largely from microfacies and wireline logs, as cores are

seldom available for the detailed study of their macroscopic features. Only two figures in the book show the use of wireline logs in subsurface facies analysis. No doubt space was the reason why these topics were omitted, and indeed the editor is to be congratulated on the way so much valuable material has been compressed into 550 pages.

There is no doubt that this scholarly book will be invaluable as a text for senior undergraduate and postgraduate students aiming for an academic career. It will also be an essential source book for all geologists concerned with sedimentary rocks.

R. C. Selley

R. C. Selley is Reader in Petroleum Geology at Imperial College, University of London, UK.

Meteorite reference work

The Nature and Origin of Meteorites. By D. W. Sears. Pp. 187. (Adam Hilger: Bristol, UK, 1978.) £13.50.

THIS is an excellent reference work on meteorites, being comprehensive in scope, yet succinct. The book is divided into six chapters. The first is a historical introduction which makes interesting reading and helps put the succeeding chapters in their proper context. I was glad that "the tortuous and sometimes confusing route by which modern classification schemes have emerged" was dealt with briefly. This is a useful chapter because it indicates how closely advances in physics, chemistry and the Earth sciences have been bound to meteorite research; and this is still true.

Chapter 2 deals with atmospheric flight and impact phenomena, including tektites, which are probably produced in rare, high energy events by fusion or vaporisation of terrestrial materials. Various casehistories of meteorite falls are given. Statistics indicate that, over the Earth as a whole, two or three meteorites arrive per day, yet samples from only about six observed falls per year actually reach the scientist. Next comes 'Classification, mineralogy and petrology'. Here the author, in my opinion rightly, concentrates on the major groups of meteorites, key references to the others being given. The scope of the chapter is, however, wider than the title implies, for estimates of the sizes of meteorite parent-bodies are included. The fourth chapter is on chemical composition and covers the observational data and their theoretical modelling and interpretation. In view of the

sometimes bitter antagonism among those engaged in the field, Sears has done well to present the different cases lucidly, with fair indication of their strengths and pit-falls. Then comes 'Physical properties and processes', including age and isotopic studies. Unfortunately there is no reference to the samarium-neodymium results which have recently made a strong impact on our understanding of the history of terrestrial rocks.

The last chapter is a synthesis of our ideas on the age and origin of meteorites. Because of its extreme brevity, uninitiated readers will have to refer to the preceding text, but most of the necessary cross-references are there.

The book is well produced and contains few errors; on p121 the seismic velocity in sandstone is given as 3,000 to 4,000 km per second (it should be m per second), and I am sure that I would enjoy studying a 'cosmogenic tract' (p148). Table 4.1, on meteorite compositions, contains numerous errors and is useless for reference. Both author and publisher are to be congratulated in producing the book so quickly that references up to early 1978 are included, but I wish that titles had not been omitted.

From the points of view of price, accuracy and being up to date, I can recommend this as a good reference text. However, in spite of the statement on the dust-cover, it will be beyond the comprehension of most amateur astronomers and geologists, and is probably more advanced than is necessary for undergraduates. It will be most useful for research students and academics; they will be unable to do better for the price.

Robert Hutchison

R. Hutchison is a Principal Scientific Officer in the Mineralogy Department of the British Museum (Natural History).

Nature Binders

**Keep your copies of Nature
protected in durable black PVC
binders:**

- * 20 plastic retention strips mean no loose parts, wire, or complex loading systems
- * title blocked in gold on spine
- * panel on spine for your own references

Each binder is designed to take two volumes of Nature; three binders will serve for a year.

Prices (including postage):
UK £3.00 each, three for £8.00
Rest of World US \$6.00, three for US \$16.00
Orders with correct remittance should be sent to:

two new journals from Alan R. Liss, Inc.

Volume 1, 1980 four issues

first announcement and call for papers

Pediatric Pharmacology

an international journal of clinical and experimental developmental pharmacology

This new journal will be devoted to the publication of original articles concerning the disposition and action of drugs in the developing organism

The journal will be multi-disciplinary: it is intended to serve as a forum for exchange of information between experimental developmental pharmacologists and clinical pharmacologists using drugs for therapy.

Manuscripts concerning the synthesis, development, mechanism of action, safety and efficacy, disposition, and

interaction of drugs as well as their effects upon the developmental process, both short and long term, will be considered. The role of factors such as environment, nutrition, and disease states in moderating the drug processes will also be covered.

Since the developmental process is a continuum from conception to senescence, articles ranging from adverse effects in the fetus on the one hand to therapeutics in the geriatric patient on the other hand are also invited.

Editor Sumner J. Yaffe • Professor of Pediatrics and Pharmacology • University of Pennsylvania • Director, Division of Clinical Pharmacology • Childrens Hospital • Philadelphia PA 19104

Gamete Research

Volume 2, 1979 four issues

Gamete biology is a highly productive and exciting field providing basic insights into such varied subjects as membrane structure and function, cell-cell interactions, differentiation, the biology of growth and development, reproduction, animal and plant breeding, genetics and reproductive engineering, the treatment of infertility, and new contraceptive technology.

This new journal concentrates in a single publication the increasing flow of research papers that, in the past, have been widely scattered among numerous journals of zoology, botany, reproduction, and medicine.

GAMETE RESEARCH encompasses all aspects of the subject, including structural, physiological, biochemical, molecular, comparative, medical, and veterinary studies. Specific topics include gametogenesis, gamete transport, fertilization and early development (including abnormalities), the preservation of eggs and sperm, techniques of in vitro fertilization and embryo culture, artificial egg activation, parthenogenesis, nuclear transplantation into eggs, gamete membranes and receptors, sex determination, and artificial insemination.

GAMETE RESEARCH is intended for researchers, medical specialists in andrology and gynecology, botanists, zoologists, animal and plant breeders, geneticists, and general biologists.

Subscriptions: \$55.00 per volume. (Additional postage outside U.S., \$5.00)

Manuscripts for consideration for both journals should be sent to the editors. Instructions for contributors are available from the editors or the publisher.

Technology

ARTIFICIAL INTELLIGENCE. (Proceedings of AISB/GI Conference held at University of Hamburg, 18th to 20th July, 1978.) Pp.x + 379. (Leeds: Derek Sleeman, Department of Computer Studies, The University, 1978.) np.

BARBOUR, R. Glassblowing for Laboratory Technicians (Including Vacuum Line Accessories and Their Applications). Second edition. (Pergamon International Library of Science, Technology, Engineering and Social Studies.) Pp.xv + 265. ISBN-0-08-022156-4. (Oxford and New York: Pergamon Press, 1978.) Hard £15; Flexi £5.

CHIGIER, N. A. (edited by). Synthetic Fuels and Combustion. (Progress in Energy and Combustion Science, Vol. 3.) Pp.ix + 271. ISBN-0-08-022122-X. (Oxford and New York: Pergamon Press, 1978.) £25.

CORNELISSE, J. W., SCHOYER, H. F. R., and WAKKER, K. F. Rocket Propulsion and Spaceflight Dynamics. Pp.xxiii + 505. ISBN-0-273-01141-3. (London, San Francisco and Melbourne: Pitman Publishing, Ltd., 1979.) £30.

ELLIS, John G., and RICHES, Norman J. Safety and Laboratory Practice. (Macmillan Technician Series.) Pp.viii + 93. ISBN-0-333-23312-3. (London and Basingstoke: The Macmillan Press, Ltd., 1978.) £3.95.

FAZZOLARE, Rocco, and SMITH, Craig B. (edited by). Energy Use Management. (Proceedings of the International Conference, Vol. III/IV, Tucson, Arizona, October 24-28, 1977. Pp.xxvii + 1111. ISBN-0-08-023219-1. (Oxford and New York: Pergamon Press, 1978.) £166 four volume set.

FRIEDMANN, Arnold, ZIMRING, Craig, and ZUBE, Ervin. Environmental Design Evaluation. Pp.vii + 225. ISBN-0-306-40092-8. (New York and London: Plenum Press, 1978.) £14.17.

GAKENHEIMER, Ralph (edited by). The Automobile and the Environment: An International Perspective. (MIT Press Series in Transportation Studies.) Pp.xiii + 494. ISBN-0-262-07070-7. (Cambridge, Mass. and London: The MIT Press, 1978.) \$35.

HINTON OF BANKSIDE, Lord. Heavy Current Electricity in the United Kingdom: History and Development. (Pergamon International Library of Science, Technology, Engineering and Social Studies.) Pp.vii + 79. ISBN-0-08-023247-7. (Oxford and New York: Pergamon Press, 1979.) Hard £5; Flexi £2.50.

HOWES, M. J., and MORGAN, D. V. (edited by). Charge-coupled Devices and Systems. (The Wiley Series in Solid State Devices and Circuits.) Pp.xii + 300. ISBN-0-471-99665-3. (Chichester and New York: Wiley-Interscience, John Wiley and Sons, 1979.) £13.50.

HOWE, J. P., and MELESE-D'HOSPITAL, G. (edited by). Thorium and Gas Cooled Reactors. (A Seminar for the 65th Birthday of Dr. Peter Fortescue, held at General Atomic Company, San Diego, California, U.S.A., 17 June 1978.) Pp.ix + 277-549. (Annals of Nuclear Energy, Vol. 5, Nos. 8-10). ISBN-0-08-024208-1. (Oxford and New York: Pergamon Press, 1978.) £20.

JENKINS, S. H. (edited by). Eighth International Conference on Water Pollution Research, Sydney, Australia, 17-22 October 1976. (Progress in Water Technology.) Pp.ix + 1060. ISBN-0-08-020902-5. (Oxford and New York: Pergamon Press, 1978.) £60.

JENKINS, S. H. (executive editor). River Basin Management. (Proceedings of the Conference held in Essen, September 1977.) (Progress in Water Technology, Vol. 10, Nos. 3/4, 1978.) Pp.345. ISBN-0-08 022938-7. (Oxford and New York: Pergamon Press, 1978.) £25.

KOHN, Robert E. A. Linear Programming Model for Air Pollution Control. Pp.xviii + 250. ISBN-0-262-11062-8. (Cambridge, Mass. and London: The MIT Press, 1978.) \$25.

MOYAR, Gerald J., PILKEY, Walter D., and PILKEY, Barbara F. (edited by). Track/Train Dynamics and Design: Advanced Techniques. Pp. xii + 469. ISBN-0-08-022153-X. (Oxford and New York: Pergamon Press, 1978.) £22.50.

NAPOLITANO, L. G. (edited by). Using Space: Today and Tomorrow. (Proceedings of the XXVIII International Astronautical Congress, Prague, 25 September-1 October 1977. Vol. 1: Space Based Industry Symposium. Pp.x + 281. ISBN-0-08-023231-0. £20. Vol. 2: Communications Satellite Symposium. Pp.ix + 158. ISBN-0-08-023232-9. £15. (Oxford and New York: Pergamon Press, 1978.)

NEWMAN, A. A. (edited by). Photographic Techniques in Scientific Research, Vol. 3. Pp.xi + 392. ISBN-0-12-517963-4. (London and New York: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) £35; \$72.50.

OXYGEN IN THE METAL AND GASEOUS FUEL INDUSTRIES. (The Plenary Lectures of the First BOC Priestley Conference, sponsored by the BOC Gases Division Trust and organised by the Chemical Society in conjunction with the University of Leeds, Leeds, September 26th-29th, 1977.) (Special Publication No. 32.) Pp.xi + 274. ISBN-0-85186-138-5. (London: The Chemical Society, 1978. Obtainable from The Chemical Society, Distribution Centre, Blackhorse Road, Letchworth, Herts.) £6.50; \$14.50.

PALMOUR, III, Hayne, DAVIS, R. F., and HARE, T. M. (edited by). Processing of Crystalline Ceramics. (Materials Science Research, Vol. 11.) Pp.xiv + 6682. ISBN-0-306-40035-9. (New York and London: Plenum Press, 1978.) £31.18.

PROCEEDINGS OF THE SEVENTH INTERNATIONAL CRYOGENIC ENGINEERING CONFERENCE. London 4-7 July 1978. (International Cryogenic Engineering Conferences, Vol. 7.) Pp.xxii + 727. ISBN-0-86103-006-0. (Guildford, Surrey: IPC Science and Technology Press, Ltd., 1978.) £33; \$85.50.

RAY, G. F., and UHLMANN, L. The Onnovention Process in the Energy Industries. (The National Institute of Economic and Social Research.) Pp.xii + 120. ISBN-0-521-22371-7. (Cambridge, London and New York: Cambridge University Press, 1979.) £6.

SAWARGI, Y., and AKASHI, H. (edited by). Environmental Systems Planning, Design and Control. (Proceedings of the IFAC Symposium, Kyoto, Japan, 1-5 August 1977.) Vol. 1: Pp.xiv + 1442. Vol. 2: Pp.xvi + 443-927. ISBN-0-08-022016-9. (Oxford and New York: Pergamon Press, 1978. Published for the International Federation of Automatic Control.) £62.50 the two volumes.

Applied biology

ADAMS, Robert, ADAMS, Marina, WILLENS, Alan and WILLENS, Ann. Dry Lands: Man and Plants. Pp.vii + 152. ISBN-0-132-22042-1. (New York: St. Martin's Press, 1979. Distributed in UK by The Architectural Press, Ltd., London.) £12.95.

AITO, A. (edited by). Conjugation Reactions in Drug Biotransformation. (Proceedings of the Symposium on Conjugation Reactions in Drug Biotransformation held in Turku, Finland, July 23-26, 1978.) Pp.x + 529. ISBN-0-444-88090-5. (Amsterdam, New York and Oxford: Elsevier/North-Holland Biomedical Press, 1978.) Dfl. 157; \$70.

ANDREOLI, Thomas E., HOFFMAN, Joseph F., and FANESTIL, Darrell D. (edited by). Physiology of Membrane Disorders. Pp.xv + 1122. ISBN-0-306-31054-6. (New York and London: Plenum Medical Book Company, 1978.) £47.25.

ANTONI, F., and STAUD, Maria (edited by). Tonsils: Structure, Immunology and Biochemistry. Pp.ix + 165. ISBN-963-05-1562-8. (Budapest: Akadémiai Kiadó, 1978.) \$14.50.

AVIOLI, Louis, V., and KRANE, Stephen M. (edited by). Metabolic Bone Disease, Vol. 2. Pp.xiii + 720. ISBN-0-12-068702-X (v. 2). (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) \$49.50; £32.15.

BARNETT, Gene, TRSIC, Milan, and WILLETTE, Robert E. (edited by). QuasAR: Quantitative Structure Activity Relationships of Analgesics, Narcotic Antagonists, and Hallucinogens. (NIDA Research Monograph No. 22.) Pp.ix + 487. (Rockville, MD.: Department of Health, Education, and Welfare, Public Health Service, National Institute on Drug Abuse, 5600 Fishers Lane, 1978. For sale by US Government Printing Office, Washington, DC.) np.

BRAZIER, Mary A. B. (edited by). Brain Mechanisms in Memory and Learning: From the Single Neuron to Man. (International Brain Research Organization Monograph Series, Vol. 4.) Pp.xv + 400. ISBN-0-89004-160-1. (New York: Raven Press, 1979.) \$39.

BROSENS, I., and WINSTON, R. (edited by). Reversibility of Female Sterilization. Pp.x + 194. ISBN-0-12-136080-6. (London: Academic Press: New York: Grune and Stratton, 1978.) £7.50; \$15.50.

CAIRNS, John. Cancer: Science and Society. (A Series of Books in Biology.) Pp.xi + 199. ISBN-0-7167-0098-0. San Francisco: W. H. Freeman and Company, 1978.) Cloth \$10; Paper \$5.

CHICHESTER, C. O., MRAK, E. M., and STEWART, G. F. (edited by). (MRAK is correct) Advances in Food Research, Vol. 24. Pp.vii + 378. ISBN-0-12-016424-8. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) \$32; £20.80.

CLARKSON, Bayard, MARKS, Paul A., and TILL, James E. Differentiation of Normal and Neoplastic Hematopoietic Cells. Book A: Pp.xiv + 1-528. Book B: Pp.xi + 529-994. ISBN-0-87969-121-2. (Cold Spring Harbor Conferences on Cell Proliferation, Vol. 5.) (Cold Spring Harbor, New York: Cold Spring Harbor Laboratory, 1978.) \$80.

COLPAERT, Francis C., and ROSECRANS, John A. (edited by). Stimulus Properties of Drugs: Ten Years of Progress. Pp.x + 572. ISBN-0-444-80087-5. (Amsterdam, New York and Oxford: Elsevier/North-Holland Biomedical Press, 1978.) Dfl. 169; \$75.25.

ELIASON, Sven G., PRENSKY, Arthur L., and HARDIN, Jr., William B. Neurological Pathophysiology. Second edition. Pp.x + 454. ISBN-0-19-502338-2. (Oxford and New York: Oxford University Press, 1978.) £5.50 net.

FAZEKAS, and KOSA, F. Forensic Fetal Osteology. Pp.414. ISBN-963-05-1491-5. (Budapest: Akadémiai Kiadó, 1978.) \$36.

GELBOIN, Harry V., and TS'O, Paul O. P. (edited by). Polycyclic Hydrocarbons and Cancer. Vol. 1: Environment, Chemistry and Metabolism. Pp.xiv + 408. ISBN-0-12-279201-7 (v.1). (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) \$37.50; £24.35.

GHOSE, T. K., FIECHTER, A., and BLAKEBROUGH, N. (edited by). Advances in Biochemical Engineering, Vol. 10. Pp.ix + 177. ISBN-3-540-08975-6. (Berlin and New York: Springer-Verlag, 1978.) DM 68; \$37.40.

GRIFFIN, C. J., and McGRATH, Philomena. Embryogenesis, Development and some Anomalies of the Upper Respiratory Tract including the Septo-Maxillary Syndrome and Its Treatment. Pp.114. (Sydney: Sydney University Press, 1978. Distributed in UK, Europe, Middle East, Africa by International Scholarly Book Services, Europe.) £12.40.

HEATON, K. W. (edited by). Dietary Fibre: Current Developments of Importance to Health. (Third Kellogg Nutrition Symposium.) Pp.158. ISBN-0-7079-6604-3. (London: Newman Publishing, Ltd., 1978.) Paper £4.50; Hard £7.50.

KRASNEGOR, Norman A. (edited by). Self-Administration of Abused Substances: Methods for Study. (NIDA Research Monograph 20.) Pp.ix + 246. (Rockville, Md.: Department of Health, Education, and Welfare, Public Health Service, National Institute on Drug Abuse, Division of Research, 5600 Fishers Lane, 1978.) np.

KRITCHEVSKY, David, PAOLETTI, Rodolfo, and HOLMES, William L. (edited by). Drugs, Lipid Metabolism, and Atherosclerosis. (Advances in Experimental Medicine and Biology, Vol. 109.) Pp.xi + 443. ISBN-0-306-40052-9. (New York and London: Plenum Press, 1978.) £23.62. (No pub. date).

LEGG, N. J. (edited by). Neurotransmitter Systems and their Clinical Disorders. Pp.vii + 240. ISBN-0-12-443050-3. (London and New York: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) £7.60; \$15.75.

LISSAK, K. (edited by). Results in Neuroendocrinology, Neurochemistry and Sleep Research. (Recent Developments in Neurobiology in Hungary, Vol. 7.) Pp.190. ISBN-963-05-1587-3. (Budapest: Akadémiai Kiadó, 1978.) \$16.50.

LUMSDEN, W. H. R., MULLER, R., and BAKER, J. R. (edited by). Advances in Parasitology, Vol. 16. Pp.xii + 376. ISBN-0-12-031716-8. (London and New York: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) £18.80; \$38.75.

McGUIRE, William L. (edited by). Breast Cancer 2: Advances in Research and Treatment—Experimental Biology. Pp.xix + 407. ISBN-0-306-33542-5 (v.2). (New York and London: Plenum Medical Book Company, 1978.) £22.05.

McGUIRE, William L. (edited by). Hormones, Receptors, and Breast Cancer. (Progress in Cancer Research and Therapy, Vol. 10.) Pp.xiii + 369. ISBN-0-89004-261-6. (New York: Raven Press, 1978.) \$35.10.

MIDDLEY, A. Rees, and SADLER, William A. (edited by). Ovarian Follicular Development and Function. Pp.xvii + 414. ISBN-0-89004-186-5. (New York: Raven Press, 1979.) \$32.50.

NATHAN, Peter E., MARLATT, G. Alan, and LOBERG, Tor (edited by). Alcoholism: New Directions in Behavioral Research and Treatment. (NATO Conference Series, 3: Human Factors, Vol. 7.) Pp.x + 403. ISBN-0-306-40058-8. (New York and London: Plenum Press, 1978. Published in coordination with NATO Scientific Affairs Division.) £22.05.

NIEBURGS, Herbert E. (edited by). Prevention and Detection of Cancer. Part 2: Detection. Vol. 1: High Risk Markers; Detection Methods and Management. Pp.xii + 1299. ISBN-0-8247-6683-0. (New York and Basel: Marcel Dekker, Inc., 1978.) Swiss francs 190.

O'BRIEN, W. M., and WISEMAN, E. H. (edited by). Piroxicam. (Royal Society of Medicine International Congress and Symposium Series, No. 1.) P.111. ISBN-0-12-523850-9. (London: The Royal Society of Medicine; and Academic Press; New York: Grune and Stratton, 1978.) £5; \$10.25.

OEHEM, Frederick W. (edited by). Toxicity of Heavy Metals in the Environment, Part 1. (Hazardous and Toxic Substances: a Series of Reference Books and Textbooks.) Pp.x + 515. ISBN-0-8247-6718-7 (p.1). (New York and Basel: Marcel Dekker, Inc., 1978.) np.

PARRISH, John A., ANDERSON, R. Rox, and PITTS, Donald, UV.A. Biological Effects of Ultraviolet Radiation with Emphasis on Human Responses to Longwave Ultraviolet. Pp.ix + 262. ISBN-0-306-31121-6. (New York and London: Plenum Press, 1978.) £15.75.

PETERSEN, Robert C., and STILLMAN, Richard C. (edited by). Phencyclidine (PCP) Abuse: an Appraisal. (NIDA Research Monograph, 21.) Pp.vii + 313. (Rockville, MD.: Department of Health, Education and Welfare, Public Health Service, National Institute on Drug Abuse, Division of Research, 5600 Fishers Lane, 1978. For sale by US Government Printing Office, Washington, DC.) np.

PINEDO, H. M. (edited by). Clinical Pharmacology of Anti-Neoplastic Drugs. (Workshop on Methods in Cancer Research held in Lunteren, The Netherlands on April 24-25, 1978.) (Applied Methods in Oncology, Vol. 1.) Pp.324. ISBN-0-444-80086-7. (Amsterdam, New York and Oxford: Elsevier/North-Holland Biomedical Press, 1978.) Dfl. 108; \$48.

REISFELD, R. A., and INMAN, F. P. (edited by). Contemporary Topics in Molecular Immunology, Vol. 7. Pp.xxi + 425. ISBN-0-306-40081-2. (New York and London: Plenum Press, 1978.) £24.88.

RUSSELL, G. E. Plant Breeding for Pest and Disease Resistance. (Studies in the Agricultural and Food Sciences.) Pp.485. ISBN-0-408-10613-1. (London and Boston, Mass.: Butterworths, 1978.) £25.

SAMIS, Jr., Harvey V., and CAPOBIANCO, Salvatore (edited by). Aging and Biological Rhythms. (Advances in Experimental Medicine and Biology, Vol. 108.) Pp.x + 342. ISBN-0-306-40031-6. (New York and London: Plenum Press, 1978.) £22.05.

SCHWALB, Marvin N., and MILES, Philip G. (edited by). Genetics and Morphogenesis in the Basidiomycetes. Pp.xi + 168. ISBN-0-12-632050-0. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) \$14; £9.10.

SLATER, T. F. (edited by). Biochemical Mechanisms of Liver Injury. Pp.xii + 821. ISBN-0-12-649150-X. (London and New York: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978.) £40.

SPAET, Theodore H. (edited by). Progress in Hemostasis and Thrombosis, Vol. 4. Pp.xv + 410. ISBN-0-8089-1096-5. (New York: Grune and Stratton, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1978. Distributed in the UK by Academic Press, Inc., (London), Ltd.) £34.50; £25.65.

Springer books in Microbiology

A Selection

Immobilized Enzymes I

1978. 48 figures, 14 tables.
VII, 177 pages.
(Advances in Biochemical Engineering,
Volume 10)
Cloth DM 68,-; US \$ 37.40
ISBN 3-540-08975-6

Contents: W. H. Pitcher Jr.: Design and Operation of Immobilized Enzyme Reactors. – S. A. Barker, P. J. Somers: Biotechnology of Immobilized Multi-enzyme Systems. – R. A. Messing: Carriers for Immobilized Biological Active Systems. – P. Brodelius: Industrial Applications of Immobilized Biocatalysts. – B. Solomon: Starch Hydrolysis by Immobilized Enzymes. Industrial Applications.

Immobilized Enzymes II

1979. 191 figures. Approx. 260 pages.
(Advances in Biochemical Engineering,
Volume 12)
Cloth DM 98,-; US \$ 53.90
ISBN 3-540-09262-5

Contents: H. M. Koplove, Ch. L. Cooney: Enzyme Production During Transient Growth – The Reorganization of Protein Synthesis. – R. D. Schmid: Stabilized Soluble Enzymes. – S. S. Wang, C. K. King: The Use of Coenzymes in Biochemical Reactors. – C. Wandrey, E. Flaschel: Process Development and Exonomical Aspects in Enzyme Engineering: Acylase–L–Methionine System. – D. J. Graves, Yun-Tai Wu: The Rational Design of Affinity Chromatography Separation Processes.

Mass Transfer in Biotechnology

1978. 95 figures. V, 151 pages.
(Advances in Biochemical Engineering,
Volume 8)
Cloth DM 58,-; US \$ 31.90
ISBN 3-540-08557-2

Contents: M. Charles: Technical Aspects of the Rheological Properties

of Microbial Cultures. – K. Schügerl, J. Lücke, J. Lehmann, F. Wagner: Application of Tower Bioreactors in Cell Mass Production. – M. Zlokarnik: Sorption Characteristics for Gas-Liquid Contacting in Mixed Vessels.

Microbial Ecology

Editors: M. W. Loutit, J. A. R. Miles
1978. 173 figures, 123 tables.
XXII, 452 pages.
(Proceedings in Life Sciences)
Cloth DM 65,-; US \$ 35.80
ISBN 3-540-08974-8

Contents: Microbial Ecology – General. – Marine Microbial Ecology. – Freshwater Microbial Ecology. – Biodegradation in Aquatic Environments. – Microbial Ecology of Soils. – Microbial Ecology of Animals: Microorganisms and the Gastro Intestinal Tract. Microbial Insecticides. – Microbial Ecology of Plants: The Rhizosphere. Plant Diseases. Rhizobium – Legume Symbiosis. – Environmental Problems Management and Control. – Microbiology of Food.

Microbial Processes

1978. 69 figures, tables. V, 144 pages.
(Advances in Biochemical Engineering,
Volume 9)
Cloth DM 58,-; US \$ 31.90
ISBN 3-540-08606-4

Contents: V. L. Yarovenko: Theory and Practice of Continuous Cultivation of Microorganisms in Industrial Alcoholic Processes. – Y. Miura: Mechanism of Liquid Hydrocarbon Uptake by Microorganisms and Growth Kinetics. – J. E. Zajic, N. Kosaric, J. D. Brosseau: Microbial Production of Hydrogen. – T. Enatsu, A. Shinmyo: In vitro Synthesis of Enzymes. Physiological Aspects of Microbial Enzyme Production.

Microbial Products

1977. 31 figures, 27 tables.
VII, 145 pages
(Advances in Biochemical Engineering,
Volume 5)
Cloth DM 56,70; US \$ 31.20
ISBN 3-540-08074-0

Contents: T.-M. Enari, P. Markkanen: Production of Cellulolytic Enzymes by Fungi. – M. Linko: An Evaluation of Enzymatic Hydrolysis of Cellulosic Materials. – R. F. Gomez: Nucleic Acid Damage in Thermal Inactivation of Vegetative Microorganisms. – R. V. Smith, D. Acosta, Jr., J. P. Rosazza: Cellular and Microbial Models in the Investigation of Mammalian Metabolism of Xenobiotics. – J. Bryant: The Characterization of Mixing in Fermenters. T. R. Jack, J. E. ANNOUNCING . . .

JOURNAL OF ECOLOGICAL AND LIFE CHEMISTRY

G+B

Edited by Derek Bryce-Smith and John Lang

The journal brings together research reports in life chemistry, which up till now have been dispersed in specialist journals of limited readership. While coverage is wide, papers are required to focus on distinct elements of chemical interest. High standard, coupled with breadth of interest and implication, imbues the *Journal of Ecological and Life Chemistry* with editorial scope extending beyond narrower specialist boundaries in biochemistry. The journal contains review articles, original papers, and short communications dealing with all aspects of the chemistry of life processes.

ENERGY AND THE ENVIRONMENT

Democratic Decision Making

Edited by
J. Surrey,

Christian Lenzer,
C. Phipps and
J. Valleix

The outcome of a lively conference at the Council for Europe in Strasbourg, this book examines the challenges facing Europe over the next quarter-century arising from the complex and interrelated problems of energy and environment policy. The stark choice confronting politicians the report says, is between on the one hand, allowing societies to maintain present life-styles and trends and neglecting the risk of future resource scarcity, and on the other hand of preparing public opinion for unpopular decisions needed to avert future crisis.

Contents

Introduction – Energy Needs, Resources and their Conservation, 1985–2000 – Non-nuclear Energy Resources and their Environmental Impacts – The Nuclear Option: For and Against – Future Policies – The Closing Sitting and Communique.

Publication: 14th December; £5.95; 0 333 25627 1

obituary

Alexander Wetmore

ALEXANDER WETMORE, who died in Maryland on 7 December 1978 at the age of 92, was for over 50 years one of the leading figures in world ornithology. Born in Wisconsin on 18 June 1886, he lived all his life in the United States, devoting his professional life to two organisations, first the Biological Survey of the Department of Agriculture (1910–1924) and from 1924 the Smithsonian Institution. From 1945 to 1952 he served as Secretary of the Smithsonian Institution, and he continued to work there after his retirement until a short time before his death.

A good many living and recent ornithologists have had new subspecies, and even the occasional new species of bird named after them; but few have had the distinction of giving their name to a new genus, such as *Wetmore-thraupis*, a new tanager of uncertain affinities discovered in northern Peru in 1963 and named by Lowery & O'Neill in Wetmore's honour 'in recognition of his many outstanding contributions to ornithology, ranging from the classification and systematics of both recent and fossil birds to such diverse facets of the subject as bird migration and pterylosis.' Indeed Wetmore's name has become a household word among ornithologists, for his classification of the birds of the world, forming the basis for the well known 'Wetmore order', has, with modifications necessitated by new knowledge, become the generally accepted arrangement, as adopted in Peters' *Checklist of Birds of the World* and other authoritative compilations.

Dr Wetmore's eminence as a research ornithologist was based on an extraordinary capacity for work, meticulous accuracy, and a very wide range of interests. When he was Secretary of the Smithsonian he customarily arrived at his laboratory at about 6 a.m. and worked steadily on his scientific projects for three or four hours before devoting a full day's work to his duties as Secretary. Up to his late 80s he continued to make regular field trips to Panama, collecting specimens and gathering information for his 4-volume *Birds of the Republic of Panama*, the last volume of which was left unfinished at his death. These qualities, applied to avian palaeontology at a time when the subject was in a state of comparative neglect, quickly made him a leading authority, his con-

tributions providing almost all that was known of the birds from the extensive Oligocene deposits of western North America. Since 1914 he described as new 189 species and subspecies of birds, a record that must be unequalled in the 20th century.

Dr Wetmore was, in a sense, an old-fashioned ornithologist, museum-based, his field work centred round collecting—one who provides the facts that others use. He did not originate new theories, seeming distrustful of the sweeping generalisation, as is often the case with those who are very familiar with the facts and see, more clearly than most, the exceptions and difficulties that need to be taken into account. Advanced though it is in the accumulation of basic facts, ornithology still needs workers of his type; they provide the infrastructure that supports the more exciting new developments.

Alexander Wetmore was a tall man of quietly distinguished presence and great natural modesty, who treated the youngest aspiring ornithologist and the older established with equal courtesy. I never heard any of his American colleagues or friends speak of him other than with respect and affection. He will be remembered by the many British ornithologists who met him at the International Ornithological Congress at Oxford in 1966, still in full vigour and only regretting that he was becoming less efficient in the field as his hearing was beginning to fail.

D. W. SNOW

Sidnie Manton

DR SIDNIE MANTON, FLS, FRS (Mrs J. P. Harding), died peacefully in hospital on 2 January 1979 aged 76. To students of zoology at the end of the last war she was already a legend.

In her first 20 years of professional life she had jointly opened the era of functional morphology with Graham Cannon in their paper on the feeding mechanism of *Hemimysis*; journeyed to Tasmania to study the endemic *Anaspides*; joined the expedition to the Great Barrier Reef and published on black corals; published on the embryology of *Nebalia*; sought-out *Peripatus* in Africa, and published on their feeding, digestion, excretion, sperm trans-

fer, embryology and life-history. A graduate and fellow of Girton, she became college director of studies in natural science, university demonstrator in comparative anatomy and later joined the staff at King's College, London. Her *Manual of Practical Vertebrate Morphology* (1930, with J. T. Saunders) was, and still is (4th edition, 1969, with M. E. Varley) the most respected and reliable guide to vertebrate dissection.

Her election to the Royal Society in 1948 crowned a distinguished career and came as no surprise. No one could have guessed that she was poised to make an even more important contribution to scholarship in the next 25 years. A gap in publication from 1938 to 1945 represents the period her young family and a heavy teaching load at Kings, Birkbeck, Queen Mary and University Colleges were making big demands on her time, but it was then she conceived and began one of the most exciting and ambitious research projects in the history of zoology. The first part of this already classic series on the evolution of arthropod locomotory mechanisms was published in the *Journal of the Linnean Society (Zoology)* in 1950 and the final part (11) appeared in 1973. The series covered 1,000 pages and included almost as many superbly executed drawings gathered into 250 compound text-figures. Functional explanations were given of many arthropod characters previously regarded as curious indications of ancestry.

She was continually in demand here and abroad, to talk about her work. At one Linnean meeting she brought along working models of arthropod legs she had made to help her own understanding; that of the spider was as tall as she, and incorporated the arcuate sclerite, a marvellous engineering device to provide the acute flexure of the femur-patella joint. The nicest device she discovered was surely the rock of the arthropod coxae, lining-up the dorsal hinge joints to translate the depression of proximal podomeres into effective extension of the legs. She was awarded the Linnean Gold Medal in 1963 before half the series was completed.

The locomotion work was certainly conceived and executed in the grand manner, but it was merely a part of

nature

REPRINTS

High-quality reprints of any paper published in **Nature** can be bought in bulk quantity (50 or more).

This service is not restricted to authors.

Typically, 100 2-page reprints would cost £18.90 (£23.50 by airmail); 1,000 would cost £41.35 (£89.70 by airmail). Covers can also be supplied.

Why not write to us for a quotation?

SINGER MICROMANIPULATORS ARE FAMOUS BECAUSE

Singer Micromanipulators enable anyone to make exact movements without tremor or lost motion, in three dimensions, using a single control handle under low or high power magnification.
A varied range available. All simple to operate.

SINGER INSTRUMENT CO. LTD.,
Treborough Lodge, Roadwater,
Somerset.

Rocks & Minerals

**SPECIMENS FOR
RESEARCH — STUDY — DISPLAY**
Bulk minerals for all purposes.
Sets of basic rocks, minerals and
radioactives. Ground Rock sections.
Advanced collectors' specimens,
fluorescents and micro-mounts.
Sets of geological specimens for 'O' and
level examinations.

Send S.A.E. for stock list.

Thermocouple THERMOMETERS

We make 14 thermometers, with digital or meter readout. All read in 2 secs, are extremely easy to use. Simply apply probe — read temperature.

Unbreakable probes are steel sheathed including World's Smallest Microprobe, 0.01" dia.

Immunologicals

Hormones

- Human glycoproteins and subunits; h GH; h PL; h TG; h Ferritins; h TBG
- Porcine and bovine glycoproteins and subunits; bovine neurophysins; rat ferritin.

Antibodies

- Antibodies to human and animal glycoproteins;
- Antibodies to Ferritins; TG; TBG
- Antibodies to gastrin; glucagon; motilin; secretin; VIP;
- Antibodies to Neurophysins;
- Antibodies against SRIF; α -MSH; γ -endorphin; PAP Complex.

Synthetic Peptides

- Angiotensins; Enkephalins;
- Endorphins; LH-RH; SRIF; TRH;
- Sleep peptide;
- Thymus circulating factor;
- Neurotensin; Bradykinin;
- Substance P; Isotocin; Bombesin;
- Litorin; α -MSH; CLIP;
- CCK-PZ fragments;
- Pancreatic Polypeptide fragments;
- Enzyme substrates.

IN PREPARATION: synthetic gastro-intestinal hormones and fragments.

Custom synthesis on request;
scale: from mgs to kilos.

A new approach in tissue culture

PETRIPERM

a novel culture dish with gas permeable membrane as cellular support.

Additional advantages of the PETRIPERM membrane are:

- UV permeable 200 nm
- Suitable for high power light and fluorescence microscopy
- The membrane can be cut for cell cloning, electron microscopy, staining and documentation
- Chemically resistant to acids, bases and organic solvents

PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.

In the intact animal, the pH and the partial pressure of both oxygen and CO₂ of the cell environment are under total biochemical and physiological control. This state is not ever approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. PETRIPERM is the prerequisite for the precise control of pO₂, pCO₂ and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable 0.02 μ m thick membrane.

Heraeus— CO₂-Incubator B 5060 EK/CO₂

We build the incubator with appropriate pCO₂, pH and pO₂ control units
